Clinical Lecture

ON

THE ADVISABILITY AND THE METHOD OF OPERATING IN CASES OF ACUTE INFLAMMATION OF THE APPENDIX IN THE PERIOD FROM THE THIRD TO THE SIXTH DAY.

Delivered at the London Hospital,

BY C. MANSELL MOULLIN, M.D. OXON.,
F.R.C.S. ENG.,
SENIOR SURGEON TO THE LONDON HOSPITAL.

GENTLEMEN,—I have taken up this question to-day for two reasons. The first is that in my opinion it is the most important question in the treatment of acute inflammation of the appendix that still remains unsettled. Everyone who has seen a large number of cases agrees now that the sooner an appendix which may be on the verge of giving way or of becoming gangrenous is removed the better it is for the patient. Everyone, too, agrees that, in the later stages of the disease, when the acute attack is subsiding and the condition of the patient improving in every respect it is advisable and safe to wait. But everyone does not agree as to what should be done in the intermediate stage of an acute attack, when the patient is seen by the surgeon for the first time between the third and the sixth day after the onset of the acute symptoms, at a time when the septic inflammation has already spread widely into the general peritoneal cavity, and there is no indication whether it is going to stop or to spread more and more widely. These are the cases that furnish the highest rate of mortality after operation, a rate so high that some have advocated not operating upon them at all, and this is one reason why I wish to deal with them to-day. My other reason is that we have had of late an unprecedented series of acute cases, even for the London Hospital, and that a large proportion of them have reached this stage before they applied for admission.

Of course, the stage of which I am speaking is not marked off by any definite symptoms from that which precedes or that which *follows it. In an attack which is fairly acute* it extends, roughly speaking, from the end of the second day to the sixth or seventh, but it is influenced by many things. In children, for instance, it begins much earlier than it does in *adults. It may begin in them within the first few hours.* Then it is influenced, perhaps more than you would think, by the anatomical position of the appendix, whether, for example, it lies behind and to the outer side of the cæcum and colon, or *hangs free in the peritoneal cavity; and, of course, it is* influenced by the intensity of the inflammation and the virulence of the organisms that are causing it. Exact definition, therefore, is out of the question, but, roughly speaking, the *third to the sixth day may be looked upon as its limits.* A very large proportion of the acute cases that come to the hospital are seen by the surgeon for the first time after they have already entered upon this stage, and I am sorry to say not a few of those which *occur in private.*

No matter what the actual number of hours may be, the clinical symptoms are usually so definite that there is no difficulty in recognising this stage when it is reached. The attitude and the aspect are characteristic. The patient lies upon the back with the knees drawn up. The eyes are ringed with black circles. The cheeks are sunken. The lips are dry and the tongue, unless there has been recent vomiting, is dry and already brown. The respiration is entirely costal. The whole abdomen is distended, hard, rigid, and motionless. The muscles are too tense and the walls too sensitive for you to be able to distinguish anything by pressure; but on light percussion the note is distinctly flatter in the right iliac region than it is elsewhere. The pulse is quick and rapid, usually over 100 to the minute. Exceptionally, in two or three instances, I have found it quite slow and fairly soft. The temperature is raised two or three degrees. Rectal examination, which should never be neglected, reveals a certain degree of fulness and tenderness, especially upon the right side. In many instances the rectal temperature is one or even two degrees higher than it is in the mouth, so high that the difference can be appreciated even without a thermometer.

Such, gentlemen, leaving out all detail, is in brief the description of the condition of the patient. It means, of course, as is patent to you all, septic peritonitis spreading from the right iliac fossa and becoming generalised. The appendix, the source of all the trouble, is either gangrenous, or has given way, allowing the liquid contents of the bowel, with perhaps a fæcal concretion, to escape into the surrounding tissue. The actual position which it occupies, and the route along which the inflammation is extending, are not known, but occasionally there is an indication of some value. An exceptionally tender spot, for instance, in the lumbar region, just over the crest of the ilium, means that the cellular tissue behind the colon is involved, and that the inflammation is tracking upwards along the posterior abdominal wall. If there is great tenderness on rectal examination, especially if it is high up, or more marked upon the right side than the left; or if there is pain on emptying the bladder with, at the same time, increased frequency of micturition, it is probable that the appendix is lying on, or over, the brim of the pelvis. If, as in many of these cases, the attack is very acute and sudden, and the whole abdomen becomes involved almost at the same time, probably the appendix is lying on the inner side of the cæcum and has ruptured into the general peritoneal cavity; and this is rendered more likely if the left side of the abdomen rapidly becomes as tender and painful as the right. But at the best all of these are only probabilities. If there is an operation they indicate to some extent where and how drainage is to be carried out. They help but little in determining whether an operation should be performed or not, and that is the point to which I wish to direct your attention to-day.

It is admitted by everyone, no matter what views he holds as to the desirability of early operation or otherwise, that operation at this stage is a very grave undertaking. The mortality is far higher than when the appendix is removed at the beginning of an attack or after the acute symptoms have subsided. But I ask you to consider with me for a moment [illegible] has supposing [illegible] far has been [illegible] the appendix. [illegible] round. Now it has reached the general peritoneal cavity. Part of this is already involved, What is the likelihood of the inflammation stopping now? What is there to make it stop? That *it does* sometimes stop there is no doubt. Every now and then you meet with a case, very rarely a first attack, in which owing to the fortunate presence of adhesions, or for some other reason which we *do not know and cannot be aware of beforehand,* the invasion is checked before it has spread too far, and the effusion becomes circumscribed. But, given the actual patient before you, you cannot calculate on pro*babilities of this kind, or treat him by percentages.* If *you* are going to leave him without operating, you must make sure beyond the possibility of doubt that the invasion has been [illegible]; the pain and tenderness abating; the temperature dropping; the tongue growing moist; and, perhaps more than all, the general aspect of the patient improving. You must not place any reliance on what you are told by the patient. In what is sometimes called, because of its deceptive character, the quiet interval, it is not uncommon for the patient and even for the patient's friends to imagine that there is some improvement, when all the time the apparent abatement of the symptoms is merely the result of the poisoning of the patient's nervous system blunting all his senses. You must be on your guard against this, and you must not pay any attention to what is told you in the face of the evidence of one single objective sign. Nothing short of a general all-round improvement justifies delay. It is not enough that the symptoms are remaining stationary or that most of them are showing signs of improvement. They must all be improving. If there is one single one about which you are in doubt, one single one that is not definitely better than it was a few hours before, the attack is not subsiding; the danger *is increasing* and you are not justified in waiting.

I have the less hesitation in speaking to you so positively on this point because I am convinced that the rate of mortality after operations performed during this stage is far higher than it need be The reason is simply that too much is attempted. The object in operating is not to get rid of the poison by a process of mechanical removal. That is impossible, if you think for a moment of what the peritoneum is, and nothing but harm can result from trying. The object is to place the injured tissues in such a position that they may be able of themselves to take all the steps that are required for their protection as rapidly and as easily as they can. This is all that can be done. Attempting to do more is only likely to inflict a greater injury. Picture to yourselves for a moment what is happening. A virulent poison, set free in one special corner of the peritoneal cavity, is overcoming all opposition and spreading wider and wider along the line of least resistance. It cannot of itself escape through the abdominal wall. There is no chance of its doing this for many days to come. It cannot escape by the bowel. Its easiest route is either through the planes of cellular tissue or in the interstices between the coils of bowel, and here it can spread, and does spread, with the greatest ease. Meanwhile the surrounding structures are making every effort to *check its further progress The walls of the abdomen and* the intestines remain absolutely quiet so as not to distribute the poisonous fluid more widely by their movements. The amount of blood flowing through the part is enormously increased. The peritoneum keeps on pouring out lymph to act as a barrier and check the advances of the micro-organisms. Vast changes, of which we do not yet know the full significance, are taking place in the blood and lymph. Unless the case is one of those fulminating ones in which the nervous system is overpowered from the first by the toxæmia, so that it can do no more, everything that is possible is being done by the blood and the tissues to check the spreading of the poison, to stop its absorption, and to rid of that which has already entered into the circulation. problem is how to help them in this. Saline fluid injected into the subcutaneous tissue or into the It dilutes the poison already absorbed and helps neys to excrete it, and there is reason to believe that sufficient quantity it may be able to reverse the pressure and check further absorption *from the surface* of the peritoneum. Nucleinic acid may be injected subcutaneously. Adrenalin may be given to raise the blood pressure. The bowels may be cleared out as soon as possible. If the nature of the infecting organism is known the corresponding serum may be injected. Even if it is not known I cannot help thinking that I have seen distinct improvement follow the somewhat haphazard administration of antistreptococcic serum. But none of these things will cure the patient so long as the poison is allowed to keep on spreading from its primary focus. Unless this is stopped, and stopped effectually, nothing else is of any avail.

The first thing to do is to lay this focus open from one end to the other so that there may be the freest possible exit through which the poison can escape. Until this is done nothing else is of any use. The spot from which the poison is spreading has to be laid bare in its whole length and breadth, so that it shall be easier for the septic fluid to escape outwards than to spread further inwards into the peritoneal cavity. The direction of the pressure has to be reversed. A free incision must be made through the abdominal wall. If there is one spot more tense or more tender than the rest the incision should run through that. Valuable information can sometimes be obtained about this, when the patient is being placed under anæsthesia, by watching for the spot from which the tenderness and rigidity are the last to disappear. If there is no localising sign of any kind the incision should run parallel to the crest of the ilium through a point one-third of the distance of the anterior superior spine from the umbilicus. But the essential feature is that the incision should be long and free through everything until the fluid pours out. There *must be no muscle splitting.* The possibility of hernia afterwards is a mere detail in cases such as these. All the structures of the abdominal wall must be divided evenly. Then the finger should be very gently passed inwards in three directions successively: on the outer side of the colon, back to the abdominal wall; in front of the colon, to its inner side; and down *into the pelvis. If there is much* fluid to escape drains should be inserted in each of these directions. I prefer a tube for the outer side of the col passed right through the abdomen over the crest of ilium, and gauze drains for the other two. But if the pat is a woman and the pelvis is involved, a tube passed thro the vagina into Douglas's pouch answers better.

That is all. The intestines should not be allowed to esc No search should be made for the appendix. If it pres in the wound, or you can get down to it at once, it should course, be removed. This is always a source of satisfact as it shows the source of all the mischief has been reach but nothing but harm results from a prolonged search for appendix at this stage. It can be dealt with later, when patient has quite recovered. No attempt should be mad cleanse or wash out the peritoneal cavity. Everythin exposure to the air, even contact with warm normal salt s tion—acts injuriously upon the peritoneal lining when i healthy, and is simply destruction to it when it is inflan There is no possibility of *getting rid of the poison* by system of washing. The attempt only distributes it ov wider area, carries the infection into regions which hitherto escaped, and does infinite harm. You have no r to feel the pulse. You have only to look at the patient's while it is being done to appreciate the effect that *so-called cleansing of the peritoneal cavity* has upon chance of recovery. And no attempt must be made to se early union of the wound in the abdominal wall. opening should be lightly packed with gauze and silkw gut sutures tied across it so as to prevent any of the b prolapsing if vomiting should set in. Later, when the ne sity for such free drainage is passed and the gauze is moved, the same sutures may be used to draw the margin the wound more closely together.

One great merit of operating in this way is that the w proceeding, if everything is got ready beforehand, need take more than a few minutes. Then the patient shoul placed in bed, lying upon his right side, with the shoul raised and the knees drawn up, and saline infusion, if it not already been started, begun at once. The length of the tubes should be left depends upon the amount of charge that comes away; but gauze drains are of no us drains after the first 24 hours. They should be remove the end of this time, and a mere wisp of gauze introd into the wound, to prevent its walls collapsing together blocking the exit. It is quite true that in cases treate this way secondary abscesses may form a few days l from foci of infection that have been left among the l of intestine; but these are merely local collections of and there is no fear then of general peritonitis setting and it is quite true that later the appendix may have t removed and another operation performed; but consequences of this kind do not merit consideration w septic peritonitis has already broken out and is rap becoming general.

THE ELECTRICAL REACTIONS BACTERIA APPLIED TO THE DETECTION OF TUBERCLE BACILLI IN URINE BY MEANS OF A CURRENT.[1]

BY CHARLES RUSS, M.B. LOND.

PART I.

Cohn and Mendelsohn, amongst other experiment submitted pathogenic bacteria to the action of the elec current to determine its germicidal value. Currents various strengths were passed through cultures and different periods; when failure to grow in subculture observed the lethal dose had been found, though it deemed difficult to decide whether the organisms were kil by the current as such or by exposure to noxious gas e.g., chlorine liberated from the electrified substances. object of my experiments is not lethal; the considerati which led to their performance were as follows. If pa genic bacteria are susceptible to electric currents travers fluids in which they are present, and such susceptibilit shown by movement to one electrode, then the elec

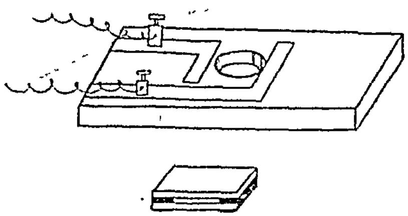
urrent might be used for their direction to that electrode
for this purpose, the electrode
ms identified. Amongst fluids
to contain tubercle bacilli are
rine, pleural effusion, cerebro-spinal fluid, or milk. The method might also be applied to the detection of typhoid acilli in water.

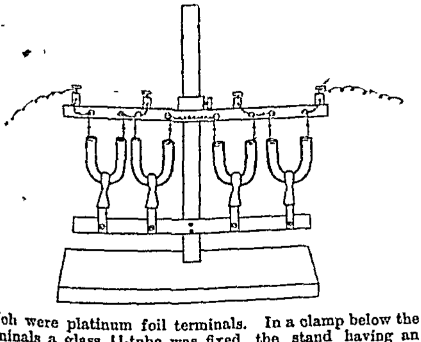
To this end I tested certain common pathogenic species in saline emulsion enclosed in a small glass cell (described ater), through which a current was passed, while observation f the organisms was made, using a microscope with 1-6th inch bjective. It was soon evident that the bacteria were moving owards one pole, a considerable aggregation of organisms t that pole becoming visible; upon reversing the current hey moved in the opposite direction. These first experiments rere carried out with the glass cell already referred to, which consisted of the following parts. Fig. 1: A cover-square was supplied with two platinum foil (or lead) terminals separated about six millimetres from each other; a lrop of weak bacterial *emulsion made electrical connexion* between the two terminals and was prevented from drying y another cover-square resting on the top of the first one, he edges of which were greased. The "glass cell" was then mounted on the stage of a microscope and a current of about one milliampère was sent through it. By observing the time required for a watched bacillus to traverse an apparent inch, and dividing by the magnification of the instrument used, some idea of their speed under these conditions was gained.

FIG. 1.



The question arose as to whether this motion might be an *effect due to some variation of the surface tension* of the fluid under the conditions of the experiment. I therefore decided to make further tests by another method in which this possibility was excluded. The apparatus used was a source of current—viz., Leclanché cells, a galvanometer, a reverser, a voltmeter, and a simple form of contact maker; having these in circuit the end wires were led to a stand (Fig. 2) furnished with contact screws, suspended from which were platinum foil terminals. In a clamp below the erminals a glass U-tube was fixed, the stand having an adjustable fastening permitting the foil terminals to be owered into the upper ends of the U-tube. An emulsion of the bacillus coli communis was made by pouring normal
saline upon a
growth by a
a test-tube w
agitation an even emulsion was then made of the bacilli.

FIG. 2.



Some of this emulsion was next poured in to nearly fill the U-tube, the platinum terminals were lowered into the limbs of the tube, so as to dip a quarter of an inch under the emulsion, and a small current was passed. By observations made at hourly intervals, organisms were seen accumulating under one of the terminals, until after several hours there was a dense column of bacteria under that terminal, visible to the naked eye as a white cloud, the fluid in the opposite limb and bend of the tube becoming apparently quite clear. Upon reversing the current similar accumulation under the opposite terminal was noticed, with similar clearance away from the terminal at which, in the *first* instance, the *accumulation* had *occurred*; the process was then repeated. It was also noticed that the aggregation became less complete with each reversal of the current. In several electrolytes of very high resistance a spurious effect was noticed. Soon after the current had been established a clearance of the bacteria from one electrode was noticed without a corresponding accumulation at the other. After stopping the current it was observed that the bacteria soon became uniformly distributed throughout the fluid in the U-tube.

The effect of a similar current was next observed with *bacterial emulsions in different salts (electrolytes)*, viz.:—NaCl, Na_2HPO_4, $NaNO_3$, Na_2SO_4. In this case equal amounts of the emulsion were poured into equal volumes of these chemicals, and by arranging four U-tubes in series their electrification was simultaneous. (I used 4 per cent. solutions of these electrolytes when in series, to enable sufficient current to pass; if the solutions were very weak—e.g., ½ per cent. or less—gravitation of the bacteria occurred before the electric effect was evident.) In such a series of observations I have found that in some electrolytes no visible effect occurs, *while in others the accumulation is evident; also that the* accumulation varies in degree with different species in the same electrolyte, and for the same species in different electrolytes. Some of these observations are set forth in Table I., and are comparative rather than absolute. If, for example, an organism is indicated by aggregation in NaCl and *nil* in Na_2SO_4, it means that by the time the effect was evident and complete in NaCl no change was apparent in Na_2SO_4. It will be noticed from Table I. that the basic

The streptococcus in Table I. died before Table II. was begun. The ? was necessitated by oxide formations referred to under choice of electrolytes.

element (sodium) is constant, while the acid radicle varies. The same species were similarly treated with electrolytes in which the acid radicle (SO_4) was constant and the base varied. The results are set out in Table II. In both tables the thin line indicates the point of cleavage of the dissolved salt under the influence of the current (primary electrolysis), the metallic radicle proceeding to the negative and the acid radicle to the positive pole respectively.

Upon the completion of the tests set forth in these tables my further work took another course, but I hope to confirm the results by repetition at an early opportunity. From the experiments indicated I concluded that these bacteria suspended in certain fluids and under the influence of a suitable electric current migrate to one of the electrodes, that they proceed on reversal of the current to the same electrode (in the opposite limb of the U-tube), and that the effecting force is sufficient to overcome gravitation; also that certain species migrate to the positive electrode in some fluids and to the negative in others. I also found the movement to occur in boiled cultures, which shows it to be independent of the bacterial vitality. In view of the object of these experiments, it may here be remarked that no consideration was paid with regard to the killing of the organisms used, either by saturation with germicides or by the currents.

Before proceeding further it will be convenient to discuss the nature of the movement just described. Amongst suggestions that present themselves to account for it are the following.

1. It is known that various forms of organic life exhibit electrical phenomena, and in the case of the electric eel the electric charges are generated in the skin. I recall, also, Dr. A. D. W. Waller's interesting demonstration of galvanic susceptibility of tadpoles. Going higher in the scale, the capillary electrometer reveals a minute change of electrical state of the human heart with each phase of systole and diastole. It must be admitted as possible that a living bacillus may also possess or generate as the result of its vital processes, minute electric charges, and if such exist it follows that these charges would be attracted to the electric pole of the opposite sign, migration of the charged object being a necessary sequence of the process.

Reference may be made here to the migration of suspended particles and of colloids under the influence of an electric current, a short account of which may be found in Le Blanc's "Text-book of Electro-Chemistry," p. 157. But against such an explanation is the fact that solutions have been found in which no movement occurs; yet through these solutions the same quantity of electricity was passing, and the facility for movement was presumably as good as in the other solutions. It is also unlikely, if bacteria possess or generate the charges postulated, that they remain in a charged condition when killed by boiling.

2. By the ionic theory in the case of a simple salt—e.g., NaCl dissolved in distilled water—the molecules are considered in the main to be united as Na and Cl atoms. During the passage of a current through such a fluid very large numbers of the molecules of the salt break up into separate atoms of Na and Cl, each with an electric charge. These electrically charged atoms or ions proceed in numerous streams in opposite directions to the negative and positive poles respectively, where they are known to be liberated as free elements, chlorine gas and sodium, which latter element at least re-dissolves in the fluid and leads to secondary electrolytic effects (which are not important for the moment). It is therefore possible that these swarms of ions are causing the bacterial aggregation under discussion, and that their possible action may be considered from two main standpoints —(*a*) mechanical and (*b*) chemical.

(*a*) Since there are innumerably more ions than bacteria, the latter are, in a sense, in the way of the ions which may push the obstructing bacteria in front of them. (Taking the length of an average bacillus at five micro-millimetres, an ion is presumed to be about 1-5000th of that size.) During the passage of the current there are two streams of ions passing in opposite directions, and if one were more efficient than the other, one would expect it to be the element whose atomic (weight) groups were heavier than the other, or whose velocity were greater (the heavy ions travel faster than lighter ones); for example, when $(NH_4)_2 SO_4$ is the electrolyte, the group SO_4 which is proceeding to the anode has an atomic weight value of 96, against a value of 36 for the groups $(NH_4)_2$ going the other way; the former group should carry the obstruction with it rather than the latter; but there are two cases shown in the table of an organism going to the electrode at which $(NH_4)_2$ arrives; further, there are several instances in which no effect was obtained in solutions whose two groups are by no means of equal weight value.

(*b*) Ions, however, if considered in their chemical attributes as free atoms, and if free during electrolysis to exert their chemical affinities, may be doing so in the effects under review; taking the case of the bacillus coli communis suspended in sodium chloride, the migration of the organism to the anode may be due to affinity of the bacillus for chlorine. If this be the case, since the chlorine atoms are impelled to the anode, it would account for the conveyance of the bacillus to that electrode. While considering this aspect of the causation the following considerations may be added:—

The speed of the bacteria should not exceed that of the ions. The speed of ions is known for certain electrical conditions, and by observations of the bacterial speed, by means of the glass cell already described, I found the velocities to be of the same order of magnitude as the calculated velocities, but further tests are desirable in this particular.

From these experiments and observations I realise that inferences as to the nature of the movement observed are useful as a working idea of the mode of action, but must be classed as speculative, and possibly further work will show that the effect is due to another cause than chemical affinity of the bacteria for these moving ions. Should it, however, be a true chemical effect it seems reasonable to expect that a series of chemicals might be found in which various, and what we know as different, bacteria should show differences of behaviour which would contribute towards the identity of members of certain bacterial groups whose differentiation at present depends largely upon their chemical actions.

PART II.

To detect the bacteria in a pathological fluid by means of a current it is necessary to cause their migration to one electrode while a current traverses the fluid, then to withdraw that electrode and identify the organisms. Two essentials are requisite, viz.: (1) the addition to the fluid of an electrolyte in which the organism is known to migrate; and (2) to arrange the electrode at which they will eventually arrive in the form of a bacterial trap.

The fluid which I selected for this application was urine containing tubercle bacilli, since the recognition of the bacilli could be made by stained films alone. The first step, therefore, was to find an electrolyte in which tubercle bacilli showed a well-marked aggregation at one electrode. This proved a laborious task, for I found it indifferent to the majority of substances in which it was electrolysed; the procedure was substantially the same as in the U-tube experiments in Part I. Tubercle bacilli from glycerine agar cultures were ground in a mortar and emulsified in water and a few drops of the emulsion shaken with aqueous solutions of numerous chemical substances and tested for migration effects in the U-tubes during electrolysis.

The conditions found desirable in the selection of an electrolyte were: (1) that it should conduct electricity well; (2) that it should be soluble in water; (3) that it should not be destructive of organic matter; (4) that it should form a colourless fluid in aqueous solution; and (3) that it should yield on electrolysis no insoluble metal or metallic oxide at the kathode, simulating or masking bacterial aggregation. The aggregation of the tubercle bacilli recorded in Table I. is a feeble one to the anode in sodium chloride, but it was considered too slight for practical use. There is noted in Table II. an aggregation at the kathode in ammonium sulphate, but that is soon followed by the appearance of a clear zone of fluid between the bacterial cloud and the platinum foil, this preventing the organisms from remaining adjacent to that electrode. This led me to believe that the bacilli if caused to approach would not remain at the electrode, and therefore could not be withdrawn for identification; accordingly, I proceeded to try other substances, of which the following is a list:—Inorganic: Potassium iodide, iodic acid, sodium sulphite, sodium carbonate, sodium bicarbonate, sodium nitrite, potassium chlorate, microcosmic salt, ammonium magnesium sulphate, ammonium magnesium phosphate, potassium cyanide, and copper sulphate. Organic: sodium tartarate, sodium acetate, sodium citrate, maltose, glucose, lactose, cane-sugar, ethyl alcohol, methyl alcohol, acetaldehyde, glycerin, formalin, formic acid, amido-acetic-acid, urea, uric acid, sodium urate, oxalic acid, urea nitrate, lactic acid, ethylamine, acetone, chloralhydrate, phenylene-di-amine, sulphanilic acid, picric acid, carbol fuchsin, chloroform, carbolic acid, acetic acid, and acetamide.

A fair accumulation at the anode was observed with iodide of potash, but discerned with difficulty on account of the liberated iodine; by the addition of this substance to tuberculous urine I recovered numerous tubercle bacilli at the anode, though they had to be liberated from a solid mass of iodine formed in the trap at the end of the process. Various other substances were added to iodide of potash to redissolve this iodine, but they all interfered with the essential bacterial movement. I therefore abandoned potassium iodide.

In the experiments recorded in Tables I. and II. the bacillus was observed to react in the presence of chlorine and nitrogen and hydrogen combinations; the selection of new substances was therefore guided by those considerations—e.g., chlorine is present in chloroform and chloral hydrate, ammonia in ammonium and uric acid compounds, and nitrogen and hydrogen combinations in the amides and amines and free acids. In many cases the substances used are poor conductors of electricity, so that only one U-tube could be electrolysed at a time with the battery power available, reaction, if any, being complete in 12 hours, another twelve being required for reversal. Eventually, with ethylamine a fair accumulation was noticed at the kathode. The electrical reaction of tubercle bacilli in normal urine alone was found to be slightly anodic.

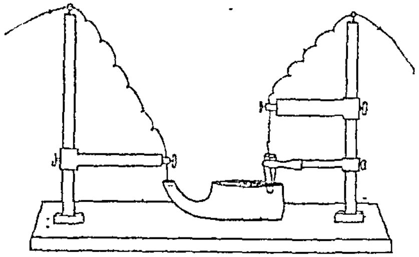
It was next necessary to find whether the addition of urine to ethylamine interfered with the observed kathodic aggregation of tubercle bacilli; the effect, however, remained unaltered. (In testing aggregations in urine I had noticed the formation of a white flocculent substance at the kathode, which is insoluble in the tube contents, but soluble in mineral and organic acids. As this substance is easily mistaken for a bacterial cloud at the kathode, the solubility in acid is a ready test for its presence; it may also be recognised by its rapid appearance and bulkiness of the cloud; in these particulars contrasting with the true bacterial massing at the electrode; lactic acid was therefore always added in urine electrolyses to prevent its formation.)

In a mixture of ethylamine, lactic acid, and urine the kathodic aggregation was found to be much stronger than in ethylamine alone, while separate tests showed no movement in lactic acid alone. Upon the completion of the aggregation stained films were prepared from the cloudy fluid at the kathode and from the apparently clear fluid at the anode; the kathode film swarmed with tubercle bacilli, and none were seen in the anode film. However, another difficulty was encountered. Although a very active electrolyte had been found in this mixture, the action had gone too far and spoilt the staining power of the tubercle bacilli (from a fresh culture); they retained the carbol fuchsin feebly and appeared very refractile. Since the recognition of tubercle bacilli from tuberculous urine was to be by stained films, their affinity for the stain must not be impaired, and means had to be found to overcome this difficulty. Two courses were open—viz., either to seek still further for an electrolyte in which the tubercle bacilli should give a good reaction, while the staining powers remained good, or to find an additional substance to be added to the urine, lactic acid, and ethylamine mixture which should "protect" the bacilli so that they should stain well at the end of the process. I chose the latter course.

In doing the tests with the 43 substances I had noticed during electrolysis of iodic acid a slight liberation of iodine at the kathode (in iodide of potash iodine is liberated at the anode), and I therefore thought that if iodic acid were added to the mixture either iodine or hydriodic acid would be liberated at the kathode simultaneously with the strongly alkaline products of ethylamine and lactic acid which form there, and that this iodine or hydriodic acid would neutralise or combine with these products which interfere with the staining power. I therefore made further U-tube tests of tubercle bacilli aggregating in ethylamine, lactic acid, and urine to which chloric acid, iodic acid, and bromic acid were also added, each in separate U-tubes; bromic acid appeared to give the best result, the bacilli taking the carbol fuchsin stain well at the end of many hours' electrolysis. The suitable electrolyte being therefore found to consist of urine, ethylamine, lactic acid, and bromic acid, further U-tube observations were then made as to the proportions of these substances which gave the most marked accumulation at the kathode. I concluded that E (1) L (4) B (2) U 1 or two parts was the most satisfactory arrangement.

Having therefore secured a tuberculous urine in which the bacilli had been found by the centrifuge, the U-tube stand was replaced by a glass vessel (Fig. 3) filled with the (B) (L) (U) (E) mixture. In the narrow limb of the vessel a platinum foil strip was submerged and served for transmission of the current through the main column of fluid. The gases liberated at this foil escaped by the narrow limb and were thus prevented from traversing the bulk of the fluid. In the other limb a glass tube drawn out to a coarse point was held also submerged slightly and traversed by a platinum wire which just touched the fluid surface. The lower end of the glass tube formed a bacterial "trap." By arranging the circuit so that the wire was the kathode, I expected that on passing a current the tubercle bacilli present in the urine and under the influence of the ethylamine and lactic acid would seek the kathode (as in the U-tube experiments), and would eventually enter the fluid enveloped by the submerged end of the tube and remain adjacent to the platinum wire. Having given them time to arrive, the wire was carefully lifted out, the glass tube was slightly lowered in the vessel, the tube top was closed by the wet or greased finger and lifted away to a slide previously smeared with fixative. The fluid in the "trap" was from two to three minims in volume and strongly alkaline at the end of the process, the bulk of the mixture remaining acid. This alkaline fluid was acidified with a 10 per cent. solution of acetic acid, placed on the slide, the film dried by heat and stained by the ordinary Z.-N. carbol fuchsin method. Tubercle bacilli were found in small numbers in the early attempts, and to confirm the experiment I attempted to detect the bacilli by this method in 12 consecutive cases, using always part of the remainder of a specimen of urine in which tubercle bacilli had been found by the centrifuge.

FIG. 3.



During these 12 experiments variations in the period of passing the current and in its strength were made. The results are shown in the Table III. and may be thus summarised: (1) that tubercle bacilli were in the "trap" upon each occasion at the termination of the process; (2) they were present in larger numbers than they would have been in from two to three minims of the original urine; (3) that they were present even when the urine had been greatly diluted; and (4) the evidence is not complete that all the bacilli in the urine used were conveyed into the "trap."

The appearance of the bacilli in the films made from the trap is similar to t[illegible] urine, although the pus cells (whi[illegible] ergo dissolution with the increasi[illegible] ontents. If the electrolysis be carried on for from 24 to 36 hours the bacilli fail to take the stain efficiently, but such exposure is unnecessary.

Comparative tests between the centrifuge and the electric current were then undertaken as follows. An emulsion of tubercle bacilli was prepared by Dr. Cavendish Fletcher by the method of vaccine making and standardised to contain 1000 tubercle bacilli per cubic centimetre; he added half a cubic centimetre of this fluid (i.e., 500 tubercle bacilli) to

The volume used by centrifuge = 10 cubic centimetres once, twice, or thrice repeated i.e., the capacity of the tube = 10 cubic centimetres. The film forms a permanent record of the experiment in each case.

100 cubic centimetres of normal urine and thoroughly mixed the fluid and bacilli and attempted to recover the organisms by the centrifuge. I added a similar quantity of the same emulsion (500 tubercle bacilli) to 45 cubic centimetres of urine and made up the volume to 100 cubic centimetres with the lactic acid, ethylamine, and bromic acid mixture, horoughly mixed the ingredients, and passed a current for n appropriate period. The result and repeat experiments are set forth in Table IV. It was thought desirable to obtain an independent examination in the repeat experiments. A sample of the test fluid was therefore sent to Dr. X. at a London hospital to be examined for tubercle bacilli.

* My sample was spoilt while starting Experiment 2.

T.B. = tubercle bacilli. In Experiments 2, 3, and 4 the estimated number of tubercle bacilli was added to normal urine and divided into three equal parts, which were then diluted as indicated. A fresh emulsion of tubercle bacilli was enumerated for Experiments 3 and 4, since the bacilli disintegrate in time. (Tuberculous urine always contains pus cells, which are much more numerous than the tubercle bacilli and carry the latter with them during sedimentation or centrifugalisation. In these test fluids there was no pus)

During the course of the work described in Part I., null experiments were occasionally made by way of control as follows. The electric circuit was arranged as usual, and an emulsion of bacilli, known to aggregate when electrolysed, filled the U-tubes, but no current was turned on. In these null experiments no aggregation was observed and the organisms slowly gravitated into the bend of the U-tube.

In the experiments in Part II., the strength of ethylamine and bromic acid used was 5 per cent., and of lactic and acetic acids [illegible] per cent., all in aqueous solutions. The average voltage of the constant current used = 15 volts, and the average ampèrage = from two to three milliampères. The time of electrolysis in the urine experiments varied from eight to 18 hours; the arrangement (of trap) described and illustrated in Fig. 3 will work automatically for two days.

I acknowledge the valuable assistance of Mr. S. Russ, demonstrator of physics, Manchester University, with the electrical technique and measurements. I am also indebted to Dr. G. L. Eastes for the use of his laboratory during the earlier part of the work and to Mr. J. G. Pardoe for a supply of tuberculous urine from St. Peter's Hospital.

In conclusion, the results of the present preliminary investigation may be summarised as follows. Certain bacteria under the influence of a suitable current aggregate at one or other electrode. The aggregation varies with the nature of the electrolyte, and is probably due to an affinity between the products of electrolysis and the bacteria. It occurs with killed as well as with living bacteria. The aggregation by electrical currents affords a means of collection and examination, and was found of greater detective capacity in certain of the experiments undertaken than was the centrifuge. The differences in behaviour of various bacteria are such as to suggest the possibility of utilising the method for purposes of specific discrimination, but in this particular the data hitherto obtained are insufficient to warrant definite statements.

Since completing these experiments I have noted the following, amongst a by no means extensive amount of published work in electro-bacteriology. Abbot and Life (*Journal of American Physiology*, 1908, p. 202) tested microscopic quantities of motile bacteria suspended in distilled water, and observed to-and-fro movements in a glass trough. They used excessively minute currents, and concluded that variations in the observed reactions of the organisms depended upon their cultivation in acid or alkaline media. They found no effects with dead or non-motile (living) species; they avoided currents large enough to cause electrolysis, and concluded that their results were galvanotropic. Apostoli and Laquerriere (*Comptes Rendus de l'Académie des Sciences*, 1901, vol. cxxxiii., p. 186) concluded that constant currents are able to sterilise cultures or attenuate their virulence. They studied especially the conditions necessary to produce such effects. S. Kruger (*Zeitschrift fur Klinische Medicin*, 1893) contributes an account of the lethal effects of electricity applied to bacteria.

THE OPSONIC TEST.

BY F. RUFENACHT WALTERS, M.D. LOND., M.R.C.P. LOND., F.R.C.S. ENG,
PHYSICIAN TO THE CROOKSBURY SANATORIUM.

SINCE the first announcement by Sir Almroth Wright of his methods for the estimation of phagocytosis and vaccine treatment there has been much controversy both here and on the Continent as to the value of the opsonic test in diagnosis and treatment of bacterial diseases. Notwithstanding the severe criticism to which the test was subjected last year at the Berlin Pathological Society, it appears to me that the main contentions of Sir Almroth Wright have been left untouched, even if the scope of the opsonic test be for various reasons less wide than was at first believed. The object of the present paper is to consider the various criticisms levelled at the test, in the light of a three years' experience of it in relation to tuberculosis.

Metchnikoff's classical experiments have shown conclusively that phagocytosis is one of the means for removing and counteracting pathogenic bacteria in the body. In some cases it is quite evident that intracellular digestion of bacteria takes place, although there are clearly some kinds of bacteria against which phagocytosis is an insufficient protection. In some cases extracellular toxins are produced—e.g., in diphtheria and in tetanus—which alone are capable of reducing the defences of the body, and which would be but little affected by phagocytosis. In other cases

—e.g., the tubercle [illegible] protected that it cann [illegible] cyte. Wright's expe [illegible] regards the tubercle bacillus and staphylococcus little or no phagocytosis happens unless the bacteria are first acted on by the unorganised constituents of the blood or lymph. Whether (as Wright contends) this action is a preliminary digestive process, or (as Baumgarten believes) a process leading to the excretion or extrusion of a chemiotactic substance which attracts the phagocytes, obviously the unorganised substances in the fluids of the body do play their part in promoting phagocytosis, and that part is an action exerted upon the bacilli. Whence these unorganised substances (which Wright calls opsonins) are derived is still an unsettled question. Allen[1] states that the amount of opsonin present in the blood bears no definite relation to leucocytosis and that it is not affected by disease of the blood-forming organs, but he does not say on what evidence this assertion is based. On the other hand, he quotes observations showing that the opsonins are derived in at least some instances from the muscle plasma. The experiments of Yorke and Smith[2] show that the specific opsonins are probably derived from a non-specific pre-opsonin. It follows from this that partial exhaustion of the pre-opsonin by the attack of one organism will leave less pre-opsonin available to counteract another. Some of my own cases appear to show that non-specific causes may also reduce the opsonic power of the blood against tubercle. Baumgarten in the Berlin debate declared his opinion that phagocytes only attack dead bacilli—meaning presumably tubercle bacilli—and that their function is limited to removal of "the corpses of the slain in battle." He asserted that the opsonins only play a subsidiary part in the fight against disease and are not the most important antibodies. He based his assertion on experiments appearing to show that there was little or no difference in lethal power between cultures treated with phagocytes, or blood serum, or both, and similar untreated cultures, but surely the relative proportions of the two sets of combatants must affect the result. In a culture there are far more virulent bacilli in a limited space than are found in an average case of disease; and it may well be that where the bacilli are in a large majority a little phagocytosis makes no appreciable difference to the lethal power. In a test tube the results are static; in the body the effect is cumulative. Metchnikoff himself has shown that the victory may sometimes be with the bacteria instead of the phagocytes; but it does not even then follow that phagocytosis is of no value, for the phagocytes may be carried with their contents to parts of the body where bactericidal action is stronger, while they protect other structures from the ingested bacilli, and may help to gain a victory for the body even though they themselves are killed.

Antibacterial action in the body is not confined to opsonins or to phagocytosis; and there is reason to believe that the spleen and the thyroid (possibly other organs) are concerned in combating bacterial diseases. If, however, the fluctuations in the opsonic index correspond with those in agglutinating and bactericidal power (as appears to be the case) the test will still be a useful clinical guide. The presumption is that all these actions are set going by the same mechanism, since they can all be started by injection of a vaccine. Even if phagocytosis were a purely subsidiary means of defence, a mere scavenging of dead bacilli, it would still be a useful guide if it were known to vary with the activity of other antibacterial actions, as it is more convenient for estimation than the alterations in agglutinating or bacteriolytic action; and there is so far no other test which quite takes its place. It has been shown that where the opsonic index is low (as in the centre of an abscess) agglutinating and bactericidal action also are low; while at the periphery of th [illegible] n, the opsonic and other a [illegible] s also been shown by A. [illegible] body temperatures in tuberculosis and some other bacterial diseases vary inversely with the opsonic index. Now a high temperature is one of the greatest hindrances to recovery in phthisis, so that what raises the opsonic index and keeps it high is likely to help recovery. Many instances are recorded where a dose of vaccine has simultaneously raised the opsonic index and lowered the temperature, recovery following. Therefore, the presumption is that the fluctuations in opsonic index are a trustworthy guide to the degree of antibacterial activity, unless the test be vitiated by difficulties in technique. That this is not so is proved by the success attending Wright and his followers in diagnosis and treatment with the help of the opsonic test.

The tuberculo-opsonic test has been criticised on the ground that a large number of indices of tuberculous individuals plotted as a curve do not greatly differ from opsonic indices of presumably healthy persons similarly treated. This criticism seems to me to be based on the misconceptions that an index within normal limits is not common in tuberculosis, and that those who appear to be healthy are all free from tuberculosis. It would be quite easy to take a thousand observations of body temperature in undoubtedly phthisical individuals which should not greatly differ from a thousand other observations in the presumably healthy, and should present much the same curve when plotted; yet nobody doubts the value of thermometric observations in diagnosing tubercle. The same is true of opsonic indices, and in both cases the circumstances have to be taken into account.

Many tuberculous patients when put to rest in the open air will begin to have opsonic indices within normal limits who previously had supernormal ones; and others encouraged to take exercise will raise a subnormal index to within normal limits. Moreover, it is extremely probable that many of the apparently healthy are the carriers of quiescent or latent tuberculous foci, and these are likely to have a subnormal index. In estimating the tuberculo-opsonic index, wherever auto-inoculation is possible, all the circumstances must be taken into account, as there may be considerable fluctuations in the course of the day, even in cases which are almost free from fever; and if the index is subnormal at one hour and above normal at another, there will be yet another hour when the index is within normal limits. Many of the recorded instances of abnormal indices in the apparently healthy may be explained by the existence of latent tubercle which we know to be extremely common. Some are doubtless due to errors in technique, since there are many possible pitfalls, some of which have not so far been recorded in the medical papers.

In collecting blood for the test it is usually convenient to choose an early hour before auto-inoculation has been started by exertion of any kind. Coughing, the exertion of dressing, deep breathing, and other slight disturbances will in many cases cause auto-inoculation and alter the opsonic index. The controls should be taken at the same hour under similar conditions as to exercise. Sometimes, however, in doubtful cases two specimens are taken before and after exercise, or before and after massage or passive motion in local tuberculosis. If the difference is much greater than in the controls, this points to the existence of a focus of disease A single control is not sufficient as a standard of comparison, as there may be a difference of 50 per cent. in the counts from two healthy individuals, and a corresponding error in the specimen for diagnosis. Care should be taken not to heat the blood in sealing the tube, as this destroys the opsonic power. Specimens which are properly sealed will keep for several days without perceptible change. French states that in ten days the opsonic index is lowered by half its original value; but from Fleming's statements[3] it appears that the rate of deterioration is not equally distributed, but is slow at first and goes [illegible] ving off the blood the [illegible] since lymph from the [illegible] x than blood from the [illegible] n a finger wet with perspiration is apt to yield a red serum which may interfere with the test. Some kinds of blood are auto-agglutinating, and this is more often the case with a red serum than with one free from hydrolysed erythrocytes.[4] Blood which is centrifuged before clotting is complete interferes with the test, as clotting then takes place in the incubator and either blocks the pipette or causes an irregular distribution of phagocytes or of bacilli. The blood should therefore be drawn off at least an hour before applying the test, and in cold weather it should be placed in a reasonably warm place to hasten clotting.

As regards the blood corpuscles, incomplete removal of the plasma will of course vitiate the test. Moreover, as phagocytosis is a vital action it will not take place properly with corpuscles which have been deadened with cold or kept overlong in adverse conditions. In cold weather the blood should be kept in an incubator at blood heat for a quarter of an hour before the test is applied. Excepting for this the shorter the interval between collecting the blood and its being used the better. If the corpuscles are left very wet they should be evenly distributed by a circular twist of the tube. Indeed, this is in any case a wise precaution. Too rapid centrifuging is stated to cause clumping of the phagocytes and to lower the index.

[4] Fleming, ibid.

In preparing the bacterial suspension a relatively strong salt solution (1·6 per cent.) should be used, as Wright has shown that weak saline solution will excite some phagocytosis even without any serum to help it. Care should be taken to avoid the entrance of other bacteria, as otherwise there may be some destruction of phagocytes or of bacteria in the incubator. Also unsterilised bacteria of more than one kind may overwork the phagocytes, whose capacity is limited. Whenever a bacterial suspension may have to be kept for some time it is advisable to sterilise it. Tubercle bacilli are agglutinated by the serum of a tuberculous patient, which interferes with the accuracy of the test. This agglutination can be prevented by heating the bacilli to 100° C. A bacterial suspension which is too thick or too thin or unevenly mixed causes misleading results. The most convenient strength is such as will give an average of three or four bacilli per phagocyte, but any number between one and ten will suffice. Where the numbers are low an extra number of phagocytes should be inspected—say, 100 or more, instead of 50 per slide. If decided clumps of bacteria are seen in the slides they should be rejected. Such a slide is unreliable and gives too low an index. In performing this test the blood corpuscles, suspension, and serum should be taken in this order, as otherwise the corpuscles or suspension may be contaminated. The most serious error of this kind is where a particular serum contaminates the other tubes. Contamination of the bacillary suspension with blood corpuscles is less objectionable than the reverse. Care should be taken to draw the suspension from the upper part of the tube and to prepare more than is actually necessary, as the lowest layers will be perceptibly thicker than the upper. In mixing the three constituents some of the phagocytes may be left behind if they are drawn too rapidly up and down the pipette. Accuracy in measuring the quantities is, of course, necessary, but with reasonable care and skill the error need not be great in this respect.

With imperfect appliances it may happen that the incubator is not kept at the right temperature. One cannot expect to obtain satisfactory results with a variable temperature, or one which is too high or too low. Also, I think it advisable to keep the pipettes horizontal in the incubator, to prevent gravitation and unequal distribution. In making the slide preparation it is essential to spread the material in a very thin film, with a definite edge well within the margin of the glass, to avoid difficulties in counting. I have found it convenient to spread in a series of jerks, making a wavy or striated film; but Wright is in the habit of making the film with one continuous sweeping movement. For some time past I have been using for a spreader a piece of glass divided lengthwise, as recommended by Allen, as it gives two edges to the film each of which can be easily examined. If the film is too thick the phagocytes remain rounded instead of being flattened out, in which case bacilli may escape notice along the edges of the phagocyte and elsewhere. Too deep a staining of the phagocyte or insufficient staining of the bacilli may also lead to errors. On the other hand, if the phagocytes are too faintly coloured they may be altogether missed. Films are easily spoilt by insufficient decolouration with acid, but such a mistake would not be made by anyone who has had sufficient practice. Wright is of opinion that the Ziehl-Neelsen method of staining destroys some of the phagocytes, and has therefore abandoned it for the aniline or fuchsin method. I am, however, under the impression that the degree of heat used with the Ziehl-Neelsen solution has something to do with the result. If the hot stain is poured over the slides in a cool photographic dish, the specimens can be well stained without any damage. This method may not be quite so expeditious as Wright's own method, but several dishfuls of slides can be fixed and stained by it in less than an hour. In counting the bacilli, the same rules should be observed for all the specimens alike. Slides with clumps of bacilli or large masses of cells should be rejected. Fragments of bacilli should either be counted as distinct bacilli or as fractions of a bacillus. Uncountable clusters of bacilli should not exist in a properly prepared specimen; if a few are present, the numbers should be estimated as nearly as possible. It is customary in some laboratories to put down each such cluster as ten bacilli. All bacilli touching a phagocyte should be included in the count.

In examining a slide it should be remembered that phagocytes vary greatly in apparent size, according to the extent to which they have been flattened out. Mononuclears, even if covered with bacilli, are best disregarded. Owing to the arrangements at St. Mary's Hospital it has been possible to do much of the counting in duplicate or by three people in succession; and judged by this check, Wright is of opinion that with reasonable care there should not be a greater error than 10 per cent. Fleming (*loc. cit.*) gives a number of comparative figures which substantiate this statement. From time to time I have had the opportunity of comparing my own work with that of other laboratories, and have found the difference in results very small.

Clinical applications of the opsonic test must be left for another communication.

Farnham.

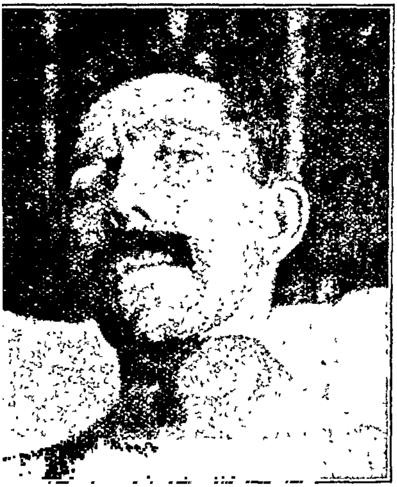
A CASE OF MULTIPLE ANEURYSMS OF THE AORTIC ARCH AND THORACIC AORTA.

BY H. EMLYN JONES, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE PHYSICIAN, LONDON HOSPITAL;
AND
T. H. C. BENIANS, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT TO THE PATHOLOGICAL INSTITUTE, LONDON HOSPITAL.

THE patient, a man, aged 45 years, a shopkeeper, was admitted into the London Hospital, under the care of Dr. Cecil Wall, on June 27th, 1908, complaining of a swelling in the upper part of the left side of the chest, together with radiating pain over the left shoulder, shooting down the left arm, causing numbness of the fingers, and hæmoptysis. The illness commenced two and a quarter years previously, when he seemed to have "cold upon cold," and finally, two years ago, suddenly brought up two to three pints of blood. He attended the hospital out-patient department, and was diagnosed at that time as "Old hæmoptysis. Consolidation of the right apex (? tubercle). Neuritis of the right cervical plexus." The patient described this pain as extremely acute, often causing him to keep his head bent towards the right side. He also had shooting pains along the right arm, similar to those he described on admission in June, 1908, as occurring along the left arm. The symptoms abated somewhat and he remained fairly well until October, 1907, when he commenced to experience the pain above described in the regions of the left shoulder and left arm.

On admission on June 27th, 1908, he complained of: 1. A pulsating swelling over the inner end of the left clavicle of about the size of a small hen's egg. This swelling was first noticed three months previously. It was very painful and tender and rapidly increasing in size. 2. Slight cough and shortness of breath. 3. A coldness and numbness of the extremities, especially the hands and feet, which he could not keep warm. 4. Hæmoptysis; small clots occasionally; no further large quantity was expectorated after the hæmoptysis at the commencement of the illness. 5. Inability to use his right eye. This was found to have been present since birth and was on account of a "congenital ptosis." The tumour had expansile pulsation, was dull on light percussion, and gave a sense of fluctuation. The skin over it was slightly reddened. The area of cardiac dulness was slightly increased, but resonance was present between this and the dulness over the tumour. The heart sounds were normal. Anæmia was marked and the superficial veins of the upper part of the thorax were slightly dilated. The pressure of the carotid pulse was 108. No pulsation was palpable at either wrist; the right temporal was palpable, but not the left. The carotid pulses were markedly unequal and asynchronous. No tracheal tugging was present, nor was there any laryngeal paralysis. The voice was somewhat hoarse, but the cough was not ısy." No glands were felt. The hands and feet were cold. There were crepitations present at both apices, ; at the right apex the breath sounds were bronchial in cter and at one spot whispering pectoriloquy was present. were proptosis and divergence of the right eye, but the ovements were free. The pupils were small but unequal :acted both to light and on accommodation. The fundi nedia were normal. There was no history or sign st syphilis. The patient was extremely temperate, ıad never done any really hard manual labour. The :rature was raised to 100° F. at night. The urine atural. Skiagrams taken on admission showed three ct bulgings of the thoracic aorta: (1) of the descend- ıorta; (2) at the junction of the transverse and ıding arch; and (3) of the ascending arch near the vhere the right innominate artery takes its origin.

sequent history.—The tumour on the left side gradually ırger until it reached the size shown in the accom- ng illustration taken a few days before death. No



[illegible] the [illegible] dilatations of [illegible]

ur was ever heard over it. It remained an expansile :ing tumour, the skin over it becoming more and more ntil, on Sept. 10th, it gave way and general oozing the sac commenced. This partially stopped for a few but a week later the large clot which had formed gave nd the patient immediately died.

ɔut four weeks previously another tumour gradually its appearance on the right side in the region of the sterno-clavicular articulation, evidently the old dilata- t the junction of the ascending and transverse arches becoming patent and approaching the surface. This ır also had expansile pulsation, but no murmur was . The radial and temporal pulses remained absent and hysical signs at the apices of the lungs practically the until death.

mary of necropsy.—Extreme anæmia. Rupture of large aneu- [illegible] portion of the thoracic aorta through [illegible] and second ribs on the left side [illegible] and separation of the first rib [illegible] of the clavicle, first rib. [illegible]

close to bifurcation. Post-mortem staining of aorta. Calcareous atheroma of coronary arteries; cerebral arteries free. Great œdema of both arms. Small patches of fibrocaseous tubercle behind and below the apex of the left lung and in the apex of the left lower lobe. Fibro-caseous nodule in the course of a bronchus behind and below the apex [illegible] mesenteric glands. Slight fibrosis of right testicle. Small polyp in splenic flexure. Mucous catarrh of stomach. No scars on legs or penis.

To the right of the sternum was a slight swelling between the second rib and the inner end of the clavicle. Immediately to the left of the sternum, over the first rib, there was a ragged ulcer of the skin; this was approximately circular, about two inches in diameter, and filled with red gelatinous clot. When this clot was removed the base of the ulcer was seen to be formed by a mass of firm yellow laminated clot in which lay the left border of the sternum, the first rib, and the clavicle. These bones were devoid of periosteum and eroded. Further, the first rib was separated from its junction to the costal cartilage, and the clavicle was separated from its sternal articulation and lifted half an inch upwards and forwards. When the skin and subcutaneous tissues had been reflected the swelling on the right side was found to be caused by a mass of soft, granular, yellowish clot, which had broken through the pectoral muscles and extended inwards on to the anterior surface of the sternum. This clot protruded through an aperture in the first intercostal space on the right side close to the sternum, and the sternum and first and second ribs in this region were devoid of periosteum and eroded.

The remov [illegible] the third to t [illegible] of the aorta, [illegible] filled the thoracic cavity almost completely and was firmly adherent to the chest wall. The dilatation was approximately of the shape of a heart, the apex of the "heart" lying at the commencement of the aorta. The greatest diameters of this sac were: vertically, 4 inches; antero-posteriorly, 3 inches; and from side to side, 5 inches. The upper border showed a mesial and two lateral convexities. The right lateral convexity was continuous with the mass of clot which had burst through the first intercostal space on the right side. From its posterior aspect arose the right subclavian and common carotid arteries, so that this portion of the aneurysm was formed, in part at any rate, by dilatation of the innominate artery. The mesial convexity was continuous with the clot which had ulcerated the skin to the left of the sternum. From the posterior aspect of this arose the left common carotid and subclavian arteries.

On opening the aorta the semilunar valves were found to be competent to the water test; the commissure and sinuses of Valsalva were not dilated. The intima of the lower inch of the ascending aorta was stained a deep red and showed large irregular yellow thickenings. There was no definite scarring. The dilatation of the aorta commenced abruptly one inch above the commissure. On the posterior wall of the dilated cavity was a Y-shaped ridge which divided the cavity into a superomesial and two lateral sacs, corresponding to the three convexities seen externally. The interior of the right sac, which corresponded to the [illegible] artery, was covered by a layer nearly one [illegible] ıite, laminated clot. This clot [illegible] through a large aperture in the [illegible] ıich lay beneath the skin to the ıight of the sternum. The superomesial sac was also lined by firm laminated clot which completely covered the apertures of the left subclavian and common carotid arteries. In the anterior and upper part of the sac there was a deficiency in its wall through which the clot passed to form the base of the ulcer on the skin to the left of the sternum. When the clot was removed from its lowermost part, in the fork of the Y-shaped ridge, an aperture of the size of a pin's head was seen which opened into the trachea 1½ inches above its bifurcation. The left lateral sac lay somewhat posteriorly to the other two; in its lower and posterior part was an aperture leading into the descending aorta. This aperture was only 1½ inches from the point where the ascending aorta commenced to dilate; it had rounded margins and corresponded in size to the lumen of the slightly dilated descending thoracic aorta. On removal of the clot the wall of the aneurysm was found to be thin. The intimal surface was smooth and showed numerous small pits.

The upper two inches of the descending thoracic aorta were slightly dilated and the intima showed slightly raised thickenings of a yellowish-white colour, cartilaginous in appearance. Between these thickenings the intima showed longitudinal wrinkles and some deep pits. On section the media was narrow and ill-defined, whilst the thickened intima was fibrotic. In the lower part of the descending thoracic aorta and in the abdominal aorta there were numerous large nodular thickenings, between which the intima showed some fine longitudinal wrinkles. These nodules were seen on section to be formed by a thickening of the intima, which was firm and cartilaginous in its upper part, but soft and yellow in its deeper layers. The media was well defined and only slightly, if at all, narrowed below the intimal thickenings. Close to the bifurcation of the aorta was a smooth calcareous plaque in the intima.

Of the four large arterial trunks arising from the aneurysm the right common carotid was the only one the opening of which was not completely occluded by the firm clot lining the sac; the opening of this artery was wide. The lumen of the right common carotid was somewhat dilated. The lumen of the left common carotid contained no clot, but was considerably contracted and in its lowest 1½ inches was barely patent. The subclavian arteries were of normal calibre.

Microscopic examination.—The aorta. Eight portions were removed for microscopic examination from the aorta on the distal side of the aneurysm. Two of these were sections of the nodules in the lower part of the descending thoracic aorta and in the abdominal aorta; they showed under the microscope the changes characteristic of atheroma. The intima was thickened and formed nodular elevations. At either side of the nodules two distinct layers could be distinguished in the thickened intima, an inner fibrotic layer, and an outer layer which contained stout elastic fibres and corresponded to the hypertrophic elastic and the longitudinal muscle elastic layers of Jores. In the nodular elevations the outer of these two layers was, with the exception of its innermost portion, entirely replaced by structureless débris, in which there was some calcium. The media was unaltered or a few of its innermost elastic fibres were destroyed. The adventitia showed no abnormality. The remaining portions were removed from the upper part of the thoracic aorta where the intima was wrinkled and pitted. They showed under the microscope the appearances of mesaortitis. The intima was thickened and consisted of stout connective-tissue fibres with very little elastic. It was seldom possible to distinguish individual layers in the thickened intima, and there was no degeneration of the connective-tissue fibres. The media was very narrow. In places it was replaced by fibrous tissue which united the intima to the adventitia; in others it contained patches of fibrous tissue, whilst its elastic fibres were swollen, tortuous, and darkly stained, and were arranged in small isolated groups. Vessels passed from the adventitia through the media to the fibrotic intima; these vessels were surrounded by a zone of round-cell infiltration, which in a few places was of considerable breadth. The adventitia was thick and fibrotic and some of the arteries showed an endarteritis fibrotica.

The liver.—Large fat droplets were seen in the cells of the periphery of most of the lobules in sections stained with Sudan. Close to some of the portal systems were small rounded granulation areas which consist of a loose network of swollen spindle cells, with numerous lymphocytes in the periphery. The centres of these areas were often necrosed and in one was a multinuclear giant cell with no definite border and with the nuclei near its centre. There were also areas in which the parenchyma was occupied by a network of fibrotic strands, most of which were connected with portal systems. These strands were formed in their central parts by connective-tissue fibres with spindle nuclei, and between the fibres were some proliferating bile-ductules and a few isolated liver cells; in the periphery of the strands were numerous lymphocytes. One or two of the strands were continuous with the rounded granulation areas. Within the meshes formed by these fibrous strands the parenchyma consisted of columns of large cells. No tubercle bacilli and no *spirochætæ* could be detected in specially stained preparations.

The kidney.—In the cortex was a small granulomatou nodule. Its centre consisted of a structureless substanc which was stained deeply by eosine and contained nuclea fragments; round this was a zone of closely packed con nective tissue cells with spindle nuclei, whilst in the extrem periphery were lymphocytes. Only one portion of th kidney was reserved for microscopic examination, and in thi no giant cells and no tubercle bacilli could be found in th granulomatous nodule.

Remarks.—The interesting features of this case are: 1 The absence of any of the usual determining circumstance of aortic aneurysm—viz., syphilis, alcohol, hard work, &c. or of any evidence of a long-sustained high blood pressure 2. The extraordinary tendency for clotting and attempts a spontaneous cure. Even when rupture took place and oozin commenced this stopped for a few days, a large clot forming until the final more extensive rupture proved immediatel fatal. 3. The old history of hæmoptysis, evidently one o the dilatations (probably that of the descending arch) ulcerating into the trachea two years previously. The ulceratio on the trachea was seen post mortem, and though old tubercl was present at the left apex, no extensive tuberculous proces had invaded the lung, making it practically certain that th large sudden hæmoptysis was of aneurysmal origin. 4. Th spontaneous cure of the aneurysm of the right side wit cessation of symptoms, followed two and a half years late by it again becoming patent after the appearance of th larger and more rapidly growing dilatation of the left side 5. The multiplicity of the dilatations.

Our best thanks for permission to publish this case are du to Dr. Cecil Wall, under whose care the patient was, and t Dr. Hubert M. Turnbull, Director of the Pathologica Institute.

A REPORT UPON THE ROUTINE USE, BY THE OPEN METHOD, OF A MIXTURE OF CHLOROFORM AND ETHER.[1]

BY FREDERIC W. HEWITT, M.V.O., M.A., M.D. CANTAB.,
ANÆSTHETIST TO HIS MAJESTY THE KING; PHYSICIAN-ANÆSTHETIST TO ST. GEORGE'S HOSPITAL; CONSULTING ANÆSTHETIST AND EMERITUS LECTURER ON ANÆSTHETICS AT THE LONDON HOSPITAL, ETC.;
AND
JOSEPH BLUMFELD, B.A., M.D., B.C. CANTAB.,
SENIOR ANÆSTHETIST TO ST. GEORGE'S HOSPITAL, ETC.

1. *The anæsthetic.*—The mixture is made of chloroform 2 parts by volume and ether 3 parts by volume. In hospital cases Duncan and Flockhart's methylated (red label) chloroform and Huskisson's "pure methylated" ether were used to make the mixture. A similar mixture was usually employed in private practice, though in certain cases one with ethyl-alcohol constituents was used for purposes of comparison.

2. *The method of use and apparatus employed.*—The mask employed (Fig. 1) is essentially a Skinner's mask and consists of a wire frame over which is stretched a single layer of thin flannel. The mask thus formed presents an oval opening, 5 inches by 3 inches and is capable of close adaptation to the face. The vault of the mask is high enough not to touch the nose when its rim rests upon the face. The size of the mask and the material with which it is covered are important details. It is found, for instance, that if two layers of the thin flannel are used instead of one an equal quantity of anæsthetic produces different effects in the two cases. The small tube passing through the middle of the stretched flannel is only of use when oxygen is required. A mask of the same dimensions, but with a guttered rim, a handle, and no oxygen tube, has generally been used by one of us (J. B.). In using the mixture a gradual process is followed. The mask is applied to the face and, after a few breaths, the mixture is added, a few drops at a time. A regulating drop bottle is used capable of delivering the mixture in isolated drops, in a rapid series of drops, or in a continuous stream. (Fig. 2.) During the first two minutes the mixture is poured upon the mask in such small quantities at a time that there is never more than a quarter

---

[1] To be presented to the Anæsthetics Committee of the British Association for the Advancement of Science, August, 1909.

of the mask moist. From this time it is added more freely until, roughly speaking, in the case of men the whole surface of the mask, in the case of women three-quarters of the surface, and in the case of children one-half of the surface, is kept moist with the liquid. As a rule at least four minutes pass between the beginning of the administration and the moment when the maximum quantity to be used is upon the mask.

3. *The nature of the cases in which the method has been employed.*—The cases in which the method has been employed include a variety of operations comprising examples of almost all the graver abdominal procedures, which were particularly chosen as providing a severe test of the efficacy of any anæsthetic and method. Thus, pan-hysterectomies, removal of double pyosalpinx, difficult appendicectomies, excisions of rectum, and "complete" amputations of breast [illegible] 'ients comprised [illegible] states of health. [illegible] police sergeant to that of the emaciated anæmic young woman, the subject of long-standing colitis. Several so-called "bad subjects" have been anæsthetised with success—for example, heavily built, florid, thick-necked men, with irritable throats and nasal obstruction, patients with ill-developed lower jaws, &c., subjects who invariably give trouble under "gas and ether." In age patients have ranged from the infant of 14 months to old persons over 80 years of age. Several patients were markedly alcoholic, others were asthmatic and orthopnœic; one patient was suffering from pneumonia, and in this case oxygen was simultaneously administered through a tube passing through the mask. One case, that of a young woman who underwent laparotomy for the removal of double pyosalpinx, was a good example of the subject who, originally favourable, is at the time of operation in a condition of extreme feebleness from acute illness of some duration. Other examples of unfavourable conditions present in the patient were Graves's disease, acute bronchitis, and extreme anæmia. We have already conducted about 300 administrations and are continuing to employ the method. The preparation of patients has varied to some extent in private cases. In hospital patients it was as follows. On the afternoon of the day preceding the operation a dose of castor oil, usually about one ounce, was given. On the morning of the operation (which took place after 1 P.M.) an enema was given at 6 A.M. Tea and bread-and-butter were given at 7—two slices and one cup. A pint of beef-tea was given at 10. The enema was repeated if necessary.

260

FIG. 1.

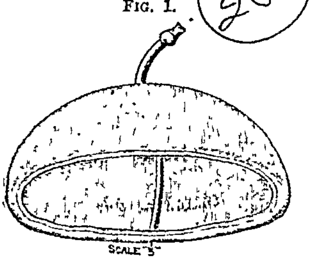


FIG. 2.

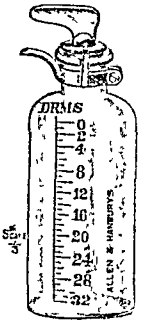


4. *The time required for inducing anæsthesia and the symptoms evoked during induction.*—Time of induction is reckoned from the moment of commencement of inhalation to the moment when the patient is ready for the operation. That this point had been reached was judged by the presence of (1) faint or absent corneal reflex; (2) complete muscular relaxation; and (3) presence of inspiratory stertor. The average induction period in a series of hospital cases was 8½ minutes; the longest time spent in securing readiness for operation was 17 minutes; the shortest time was 5 minutes. With children 5 minutes was the rule, and this was the time also in the case of a woman very anæmic and ill with peritonitis. The longest induction period was in the case of a middle-aged carman, red faced and accustomed to large amounts of beer, who had to be operated on for fistula in ano.

At the beginning of inhalation the vapour is not, as a rule, objected to, particularly if constituents made from ethylic alcohol be used. There is never any difficulty in getting patients to breathe freely. Excited talking, becoming incoherent, or quiet busy muttering occurred in 10 of 40 hospital cases. Some rigidity of limbs and of jaw muscles occurred in 18 of these cases. Excited movements of limbs or trunk so forcible as to require restraining lest the patient should fall off the couch occurred in 1 case. Excitement of the above kinds when it occurred at all was always after consciousness had gone—at any rate, to such an extent that the hearing was already quite lost. Secretion of mucus and saliva is not a feature of the induction stage with this anæsthetic. In difficult cases there is less temporary interference with respiration during the induction stage than when employing ether or "gas and ether."

5 *Amount of mixture required.*—Generally speaking, it is found that in the case of an adult male the mask has to be kept moist over its whole surface after the first four minutes until full anæsthesia is induced. After this it is necessary to keep it moist to that extent only in the case of "difficult" subjects. In the case of easier male subjects and in the case of women and of children only half of the mask is kept moist when anæsthesia is once established. In the case of children and women who are particularly feeble never more than half the mask is moistened from first to last and most of the time only a quarter. In a series of hospital cases the average amount of the mixture consumed was one ounce in 14 minutes; the least used was half an ounce in 22 minutes (feeble infant); and the most used was three and a quarter ounces in 30 minutes (fat alcoholic woman).

6. *The condition of the patient during operation and the occurrence of shock or other reflex effects.*—A condition which is highly satisfactory with regard to the state of the circulation, the respiration, the relaxation of muscles and the immobility of the patient can almost invariably be obtained and maintained. Respiration is usually rather deeper, the pulse quicker, and the colour better than in average chloroform cases. The pupil is usually of moderate size. In one case only was a change of anæsthetic demanded. In this case, during the removal of a gall-stone, a condition of persistent rigidity of the rectus led to a change from the mixture to ether (F.H.). In cases with marked respiratory defect the mixture may be given with oxygen. The type of anæsthesia obtained is more like that secured by low percentages of chloroform vapour than like that seen with ether. It is generally possible to secure a condition in which the corneal reflex is just present without the occurrence of inconvenient contraction of muscles or of coughing or retching. Reflex effects due to the operative procedure have been noted in several cases. Serious disturbance of pulse or of breathing arising in this way appears to be less liable to occur with this mixture than with pure chloroform, though more likely than when ether alone is given. Reflex effects during anæsthesia, chiefly bearing upon respiration, were evident in 15 of 75 carefully recorded cases. In most cases these effects were in the nature of stridor or of grunting expirations. They occurred during stretching of anal sphincter, forcible pulling up of uterus, internal urethrotomy, &c. The most marked instance of respiratory effect was produced by dragging upon the sac of a hernia and this case afforded an excellent example of the degree to which such an effect can go, respiration becoming absolutely obstructed and the chest having to be compressed three times before breathing started again. At the same time the pulse scarcely showed any change. Reflex movements of limbs or reflex rigidities of muscle were very rarely met with and this absence was particularly noticeable in rectal operations which, under ether, are frequently attended by such reflexes. Slowing of pulse as a reflex effect was occasionally observed. In a few cases well-marked pallor occurred during surgical manipulations. Severe surgical shock, resulting in disappearance of pulse, dilatation of pupils, opening of eyes, pallor, and stopping of respiration, was seen in one case, in which laparotomy was being performed upon a thin anæmic young woman, the subject of extreme chronic constipation. The

corneal reflex was faintly present at the moment when symptoms of shock suddenly showed themselves.

7. *After-effects.*—Speaking generally, recovery takes place rapidly and without any disagreeable after-effects, provided, of course, that the patient has been properly prepared. In no cases of our series were there severe after-effects. The worst instance was that of a case of removal of glands from a young man, aged 25 years. In this instance there was vomiting seven times during the first 14 hours after recovery of consciousness. Liquid nourishment was taken between the attacks of sickness and there was no serious constitutional disturbance. In several cases there was vomiting once or more after recovery of consciousness. In one of these the vomit consisted of altered blood on the two occasions on which it occurred; this was a case of gastro-enterostomy. In practically all cases there was, 24 hours after operation, complete freedom from sickness and from feeling of nausea. Our belief is that after-effects are less common with this method than with most others now in use.

8. *Conclusions.*—Our experience leads us to believe that this mixture used in the particular manner described is a trustworthy and comparatively safe anæsthetic. By this we mean that if the simple principles are adhered to of starting gradually and limiting the moistened area of the mask over-dosage is very unlikely to occur. It seems to us highly probable that the percentage of chloroform vapour thus offered to the patient is within the safe physiological limits. Moreover, the danger of post-anæsthetic lung complications, which detracts from the otherwise safe nature of a similar ether anæsthesia, is apparently no greater than is the case with chloroform. In our judgment the fact that even the most vigorous subject may be anæsthetised by this mixture on an open mask marks a distinct step in the progress of practical anæsthetics. The Rendle inhaler, and all similar semi-open inhalers for the A.C.E. or the C E mixture, should, in our opinion, now be discarded. The method described seems to us to contain the advantages of open etherisation with those of percentage chloroformisation, although, of course, it does not pretend to absolute scientific accuracy so far as vapour percentages are concerned. By this method chloroform is rendered safer than when administered *per se* on a Skinner's frame and very much safer than when administered on lint or towel. We go so far, indeed, as to express the view that the administration of undiluted chloroform by means of lint, handkerchief, or towel should henceforth be proscribed in practice. The anæsthesia produced by this method is doubtless a chloroform anæsthesia in its essential features, but the dilution with ether renders it possible to present continuously a weak and comparatively safe chloroform percentage to the patient. Moreover, this mixture may, with the rarest possible exceptions, be used whenever chloroform itself is indicated. But it has advantages of another kind. It answers admirably and certainly far better than ether in so-called difficult cases, particularly in those liable to display symptoms of obstructed breathing during induction and in those in which the secretion of mucus would constitute a difficulty. As a substitute for the "gas"-ether-chloroform sequence this mixture and method have much to be said in their favour. We have come to the conclusion, indeed, that some of the slight difficulties experienced by the anæsthetist in securing the most favourable surgical conditions during abdominal operations are often dependent upon the presence of small quantities of mucus within the upper respiratory passages resulting from the use of ether during the induction stage. Though rapid induction may be depended upon by "gas and ether" or similar methods before proceeding to chloroform or C.E. mixture, a penalty often has to be paid, so to speak, for this rapid induction—viz., some disturbance in the smoothness of the subsequent anæsthesia. Although the method here advocated has the disadvantage of a comparatively lengthy induction the eventual type of anæsthesia is highly satisfactory. In a word, we have no hesitation in recommending this mixture, administered by means of the particular mask and method we have described, as one which is capable of a wider range of applicability in general surgery than any other anæsthetic or mixture with which we are acquainted. Whilst the anæsthesia we have attempted to describe is undoubtedly safer than that produced by sprinkling undiluted chloroform upon lint, towel, or any form of open inhaler, we do not contend that it is safer, *whilst the patient is upon the operating table*, than ether anæsthesia. If, however, we take into account risks of ether anæsthesia *after the operation* we are of opin that the method compares favourably with all kn methods of etherisation, so far as safety is concerned.

HIGH-FREQUENCY CURRENTS AND THE MEDICAL APPLICATION.[1]

By C. FRED BAILEY, M.D. LOND., M.R.C.P. LOND. D.P.H.,

ASSISTANT PHYSICIAN, SUSSEX COUNTY HOSPITAL, AND MEDICAL OFF
IN CHARGE OF THE ELECTRICAL DEPARTMENT.

IN January, 1898, D'Arsonval first described his meth of applying electric currents of "high-frequency" or "h potential"—i.e., tension or pressure—to the human fra so their medical history is but a matter of nine or ten ye True, the oscillatory nature of the discharge of a Ley jar or a condenser under particular conditions (origin pointed out by Joseph Henry of Washington) was mat matically expressed by Lord Kelvin as far back as 1853, for practical purposes the application of high-freque currents in the treatment of disease is quite a recent aff The D'Arsonval treatment, like any other new meth passed first through that stage in which it is vaunted a panacea for almost every disease, to be followed by period of universal depreciation where it is reckoned of value at all. The first corresponds to the time that a tr ment is carried out almost solely by its originator and a able assistants or pupils; the next to its exploitation b host of more or less unskilled persons.

High-frequency treatment now enters on the third st where discrimination is possible between the cases wher is beneficial and those where it is decidedly injurious or e dangerous. The physiological action and effects of currents have been studied at length both on animals man; contradictory results obtained by different obser have been or are being brought into line, and we are no possession of a working hypothesis which gives us (1) indications for use or avoidance in different varieties disease, and (2) the particular form in which, where it i value, it is to be applied to obtain beneficial results.

In a paper on high-frequency currents it is as w perhaps, to recall to your memories their true nat Briefly speaking, they are "succeeding groups of elec oscillations produced by the discharge at intervals o charged condenser." [Dr. Bailey then shortly described usual method of producing these oscillations, and tinued:—]

The currents of high frequency, produced in a mod apparatus, possess a potential (tension or pressure) of perh 10,000 volts; they are alternating (alternately positive negative), changing their sign in the short period of millionth or thereabouts of a second. According to amount of current passing they give readings on a hot-w milliampèremeter up to a thousand milliampères. Th travel with the same velocity as light, x rays, and transverse vibrations of the ether—i.e., 300,000 kilome per second—and they possess a wave length of from metres to 30 centimetres. It is manifest that if the organ be permeated by currents of such tremendous pressure an rapidly alternating it must be in a state of microsc vibration in which there is no time for a muscle or ne (or macroscopic part of muscle or nerve) to be sufficie stimulated by a positive or negative charge of electricit produce the effects the ordinary galvanic, faradic, sinusoidal currents cause. There is no time for a respo either sensory or motor, before the whole conditions positive or negative sign, &c., are reversed. Neverthel every cell or fibre of the organism is undergoing microscopic battering or massage under the influence the current, and to this microscopic battering, no dou the physiological effects are mainly due. Motor sensory nerves respond only to electric stimuli wh period is not less than one-ten-thousandth of a second, period of high-frequency currents being but one-hundre to one-ten-thousandth of this; therefore we find that on one hand they produce neither any immediate pain or ot sensory effect, nor on the other do they cause any muscular contraction of voluntary muscles.

---

[1] A paper read before the Brighton and Sussex Medico-Chirurg Society.

The exposure of the neuro-muscular system, however, to these enormous differences of electric pressure of an oscillatory character does gradually induce the condition termed "inhibition"—i.e., the onset of a state in which stimuli, normally capable of exciting response, have no effect whatever. If the electrode of a high-frequency apparatus (attached to the end of the resonator which gives currents of high pressure rather than quantity) is placed in an arm-bath filled with warm water, the arm of an experimentee being placed in this and a current of 100 milliampères passed into the water for three or four minutes, the arm becomes blanched dead white up to the upper limit to which the warm water extended, the skin insensitive to a needle and numbed, and there is great loss of muscular power, and it takes an appreciable time and vigorous rubbing to dispel these results of the experiment. The electric tension of the water in the bath is great enough while the current is passing to give a half-inch spark if the finger is brought near it.

For practical purposes of value the applications of high-frequency currents may be divided into two varieties: (1) the method where large currents (in "auto-condensation," up to 1000 milliampères, an average being 350 milliampères) pass through the body; and (2) the method where the electricity is applied under very *high pressure* but the quantity is comparatively small; such are the effleuve and the electric spark—these latter are the more especial "high-tension" applications. The first type, the *quantity* type, produces effects which in many respects differ from the second or *tension* type; this is most evident in reference to vascular tension, for while "auto-condensation" causes general vascular dilation, flushing, sweating, and general hypotension, the "effleuve" causes spasmodic contraction of the skin vessels, goose skin (the intrinsic involuntary muscular fibres of the skin undergoing contraction), and a general rise of blood pressure of a variable degree, but most marked when the brush discharge is applied to the cervical and upper dorsal spine. The extreme effects of a high-tension current applied locally by an *arm-bath is an example*, the condition resulting being comparable to the "local anæmia" type of Raynaud's disease.

Dr. Doumer of Lille, in a paper read before the Electro-Therapeutic Section of the Royal Society of Medicine, pointed out that the study of electricity in the form of high-frequency or high-tension currents will be likely to lead to more valuable results than the investigation of other forms of electricity which produce, and the effects of which are masked by, secondary phenomena and their effects. "Continuous (or galvanic) currents," he says, "cause electrolysis and migration of ions—interrupted (or faradic) currents, muscular contractions—these may mask physiological effects produced exclusively by electric energy. High-frequency currents produce no chemical effect, no sensation, no muscular contractions, nevertheless they do cause manifest definite general biological effects. The organism is plunged into an oscillating magnetic field, giving rise to currents equally oscillating in the deeply seated tissues, which do not, however, produce any permanent displacement of the ionic masses." *He concludes, first*, that electric energy by itself, from the results of experiments on germinating seeds, does cause an increase of cellular vitality with an increase in the nutritive exchanges—i.e., it has a real action on the living cell, increasing vital exchanges, heat production, respiratory exchanges, excretion of effete products, this quite independently of action on a vascular system; secondly, that electric energy does act in reducing local congestion by its decongestive action; this has been shown experimentally: if the inter-digital membrane of a frog's foot be inflamed by the application of a drop of sulphuric acid the effleuve will cause the stenosed vessels to release themselves, the dilated vessels to contract, the circulation becoming normal when the vessels have resumed their normal calibre; thirdly, electric energy does produce a general action on the whole vascular system, which action varies according as the quantity or the tension of the electricity is a predominating factor, great quantity leading to hypotension, great potential or pressure to hypertension of the whole vascular system; and fourthly, it causes the phenomena of "inhibition"—anæsthesia of sensory nerves and inexcitability of voluntary muscles.

These four physiological actions being now recognised—viz., increased cellular activity, local decongestive action, alteration of general vascular tension, and inhibition—we shall be led to treat diseases or conditions where these physiological results are beneficial and to avoid those where they are hurtful. We can study our cases and formulate an opinion as to whether the good effect produced by one action may be counterbalanced or overshadowed by the prejudicial effect of another action, or we can so modify our remedy that one effect is produced while another is almost suppressed, and so on.

Auto-condensation.—Treatment by this method is carried out by placing the patient either recumbent on a couch or, better, sitting on a bent-wood easy chair on which is a long mattress cushion stuffed with rubber waste, the patient being thus insulated by the rubber cushion and an insulated foot-stool. A sheet of iron covers the chair-back. When the patient and the sheet-iron are severally attached to the two proper terminals and the "quantity" current applied, the patient and sheet-iron become parts of a "condenser" (the rubber cushion being the di-electric), hence the term "auto-condensation." A certain class of individuals who are subject to more or less continued vascular hypertension are benefited, temporarily at first, but after a while permanently, by this treatment. Many of these cases perspire, even in very hot weather, only on quite extreme exertion; their heat-regulating centres do not work, they feel surface-cold in winter and are prostrated by heat in summer. By auto-condensation the vascular tension is reduced, as measured by the Riva-Rocci instrument, some millimetres. Headache, a common symptom, is much relieved or abolished.

[illegible] rs from
sion by
(gr. 5)
which
itil the
ur, and
au lie-
urrent
, eight
former
symptoms.

CASE 3.—The patient was a woman, aged 60 years. Symptoms: giddiness, sleepiness, great depression, occasional "wandering," memory failing, onset gradual. Arterial tension found to be 160 millimetres. Condition returned to normal with 12 treatments, combined with dietetic and medicinal measures.

In two patients who felt extremes of heat and cold very severely, and whose circulation was evidently very defective, a method was used which gave excellent results. This was to give auto-condensation for ten minutes in order to dilate the vessels and immediately follow it by ten minutes' high-tension effleuvation to the cervical and upper dorsal spines to cause vascular contraction on the principle of exercising the vessels and stimulating the heat-regulatory centres.

High tension.—For general application of this type of current the patient is best seated in the chair and insulated by the rubber cushion and foot-stool. He holds a metal electrode as in the case of auto-condensation, but this is attached to the top of the resonator, and the other end of the resonator is connected to earth by an earth-wire. Neurasthenics, who commonly suffer from arterial hypotension, are best treated by this method; they should never have auto-condensations, or only exceptionally. Of six cases of neurasthenia, a cure resulted in two and two were improved.

CASE 4.—The patient was a woman, aged about 35 years, holding a very
onerous pu [illegible]
engagement [illegible]
100 millime [illegible]
under 12 treatments, current of 150 milliampères, and eventually was able to resume her duties as before.

Effleuration.—Here the high-tension "brush" discharge is applied locally by means of a special electrode. This is a rosette of metallic points attached by a rubber-covered wire to one end of the resonator, the resonator being a coil of thick copper wire in which the tension of the current is extremely high, so high that an abundant shower of two-inch sparks is given off from the rosette. Beyond the sparks the discharge (or effleuve) extends for four or five inches as a flame-like band which in the dark is seen to be violet in colour and is made up of large quantities of violet and ultra-violet rays. It causes a sensation like a rain of warm sand, a tingling in the limb treated, and minute fibrillary contractions of the muscles. Its chief value is in painful neuritic affections, and the larger number of patients one has to treat are sufferers from neuritis. We have here a condition of subacute or chronic inflammation of a tissue, the nerve, usually fairly deeply situated. By effleuvation we are able to modify this condition and to produce vascular changes in the nerve leading to the excretion of effete materials which may be irritating it; at the same time we reduce its hyperæsthetic condition. Most cases of rheumatic or gouty neuritis, the latter especially, are cured with more or less rapidity according to their chronicity.

During the last few years I have had sent to me many neuritic cases, principally brachial neuritis; all had previously been for longer or shorter periods on drug treatment without benefit, and a fair percentage of these were rapidly cured by effleuvation. Of eight cases of brachial neuritis treated during the past year four discontinued treatment (one after one application, three after two applications) for various reasons, and so did not give the remedy fair trial, but the remaining four were absolutely cured in from six to ten treatments. Practically in all these four cases the history of the effects of the "brush" discharge treatment was the same; after the first application there was definite slight relief—this was more marked after the second; after the fourth or fifth the pain was negligible, and the patient considered himself or herself well after the sixth or seventh.

CASE 5.—The patient, a man, aged 60 years, had pain in the neighbourhood of an old united dorsal angular curvature spreading along the intercostal nerves on either side; it appeared in all probability due to some fibroid-tissue contraction about those nerves. Treatment, effleuve to area of pain, 19 applications of 20 minutes, removed pain altogether.

After the *first* application of the effleuve, the immediate effect is often abolition of pain; this is due to "inhibition." After a variable number of hours this "inhibition" effect passes off, and, as a result of vascular and other changes set up in the nerve, the pain returns often rather acutely, and is worse for five or six hours. It is well to warn the patient of this in order that he may not be discouraged. By the next day, however, the pain in the limb or part is, as a rule, decidedly better than it was before the first treatment. This initial increase of pain does not occur after the second or later treatments.

There is a point of interest about the effleuve application, as I have said, in that it consists of a very large amount of violet and ultra-violet rays. These latter are believed to have a marked good effect in treatment of skin eruptions which have a microbic origin, and it is quite a usual thing to see an area, treated for neuritis by the effleuve, rapidly clear itself of an eruption, like acne, while the untreated part remains unaffected.

Sciatic pain, if it is neuritic and not referred pain, is often quite rapidly cured in two or three treatments, especially if its onset is recent. Cases of myalgia, so-called, such as the common stiff-neck, are usually abolished, as far as pain is concerned, almost at once. A woman, with sudden stiff-neck, only able slowly to turn her head with much pain, in 15 minutes could move it in all directions easily, and there was only a little stiffness but no pain on the following day.

In skin affections, where there is inflammation of a chronic type, we can alter this by effleuvation, we can diminish local blood-supply to inflammatory patches in eczema, erythema, &c., while stimulating the cells to increased activity, at the same time diminishing the hyperæsthesia and the itching. In pruritus the effleuve I have found of great value. A case in point: A patient with intolerable itching of the legs which had kept him awake most of each night for some weeks. There was a patch of dry eczema of long duration on the right arm, but the legs themselves were free from eruption. He had tried every conceivable remedy without much effect. I was sceptical of producing any good result, but gave ten minutes application of effleuve over each of the legs, which were then itching violently. The irritation was abolished there and then, and it had not returned some days afterwards.

The application of the high-tension current by metal electrodes to the anus in anal fissure, hæmorrhoids, and pruritus ani has been found of marked benefit both to alleviate and to cure. Old-standing varicose ulcers treated by the effleuve lose their thickened edges and develop a granulating surface, healing rapidly. Prostatic hypertrophy is said to be diminished; I have no experience of this, but one can understand that it is likely to be so if one bears in mind the so-called local decongestive action. I need not continue because, although high frequency has been tried, and apparently with benefit, in many other affections, it has been used very empirically and without any definite relation to a physiological result to be sought for.

I conclude by reiterating this. Experiments on animals and plants, observations on human beings, *not* founded on the individual experimentees' own statements, show that there are *four* marked effects of electric energy produced, uncomplicated by chemical effects, by high-frequency currents: (1) Increased cell activity, increased metabolism; (2) return of a locally inflamed tissue to its normal; (3) either general vascular dilatation or contraction, according to the particular method used; and (4) "inhibition," diminished sensory or motor excitability. So that where one or more of these effects is or are desired and where the remaining effects are not prejudicial, or can be very much diminished or abolished, there high-frequency treatment may be of real value, and for these reasons has a prospect of considerable therapeutic use in the future.

Brighton.

A CASE OF MULTIPLE INTRACRANIAL TUMOURS WITH INVOLVEMENT OF BOTH AUDITORY NERVES.

BY GEORGE NIXON BIGGS, M.B., B.S. DURH.,
AURAL SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK BRIDGE ROAD, S.E.; ASSISTANT SURGEON IN THE EAR, NOSE, AND THROAT DEPARTMENT OF THE SEAMEN'S HOSPITAL ("DREADNOUGHT"), GREENWICH.

THE patient presented himself at the out-patient department of the Seamen's Hospital, Greenwich, on Nov. 11th, 1908, complaining of deafness of ten months' duration in both ears, the condition being most marked on the right side. There was no tinnitus, but there had been persistent right-sided headache for ten months, and for the last five months the patient had had attacks of vertigo. There was no sickness and no paracusis Willisii was present. On examination of the ears both membranes were found to be slightly indrawn and the cone of light was just broken at the periphery. With Siegle's speculum the movements of the membranes and mallei were found to be normal. The Eustachian tubes on catheterisation were found to be normal. Nothing unusual was found in the nose or nasopharynx. Nystagmus was present, the movements being equal in both directions. Both pupils reacted to light and accommodation, and double optic neuritis was present. There was no facial paralysis and no incoördination was noticed on rapid rotation of the hands. On walking the patient swayed laterally and the feet were kept far apart; there were no stamping and dragging. On standing erect with feet together and eyes closed he swayed from side to side. He had met with an injury though the falling of a bucket on the right parietal region five months previously, and a scar was present on the parietal eminence. There was no history or any sign of syphilis. On testing the hearing the following results were obtained:—

RIGHT.	TESTS.	LEFT.
—	Weber.	Deflected to left.
On mastoid.	Acoumeter.	Contact.
0	Voice.	Four feet.
0	Whisper.	0
Negative.	Rinné C.	Negative.
Negative.	Rinné C^2.	Positive.
– 30 seconds.	C. mastoid.	– 25 seconds.
Positive.	Gellé.	Positive.
	AIR CONDUCTION.	
Not heard.	*3C 16*	Not heard.
	2C 32	"
	1C 64	"
	C 128	Perception.
	C^1 256	Very much diminished
	C^2 512	" "
	C^3 1024	" "
	C^4 2048	" "

As the patient was obviously suffering from an intracranial tumour and there was almost complete nerve deafness on the right side, whereas on the left side it was not nearly so advanced, I sent the case into the hospital as either a tumour of the right auditory nerve or of the anterior part of the cerebellum pressing forward on the auditory nerve. The patient was admitted under the care of Dr. S. Russell Wells.

His state on admission may be summarised as follows. The hand-grasps were found to be equal and good. A slight lateral tremor of the hands on extension was present. Coördination movements were good. The knee-jerks were exaggerated. The elbow reflexes were fairly good. The plantar reflex was rather slow, but on the whole there was flexion. No ankle clonus; no nodes on tibiæ. No apparent diminution of sensation; no tenderness of the calves of the legs. There was no incontinence. No sign of disease was found in the chest or in the abdomen. Mr. R. E. Bickerton, who kindly examined the patient's eyes, reported as follows: "Nystagmus is present, there is no paralysis of any of the extra-ocular muscles, [illegible] 9. L., 6/9. Both fields of vision [illegible] is slightly larger than the left, [illegible] ic neuritis is well marked in both and there is a hæmorrhage above the left disc. The right optic neuritis looks of longer standing than the left, but the left appears to be increasing; there is much exudation above both discs. The right is seen with spher. + 3·5, left with + 3; there is more swelling of the right disc than of the left." On Nov. 16th there is the following note: "The palate is peculiarly insensitive, and the left side moves better than the right. There is perhaps slight weakness of the right orbicularis palpebrarum muscle. Face muscles the same on both sides. Fifth, no alteration on either side. On the right parietal region just above and behind the ear there is a slightly tender spot." Mr. Laurie H. McGavin, who saw the case in consultation with Dr. Russell Wells, agreed with the diagnosis and an operation was decided upon.

On Nov. 17th an operation was performed by Mr. McGavin. Chloroform having been administered, a large flap was turned down [illegible] region, the top of the [illegible] the superior curved l [illegible] from an emissary vein close to the mastoid. A trephine was placed over the cerebellar region and a piece of bone was removed. The dura mater bulged and there was no pulsation visible. The bone was removed with forceps until the greater part of the cerebellar area up to the middle line had been cut away, while above it was carried well up beyond the lateral sinus, so that the difference of tenseness of the dura mater above and below the tentorium, which was very striking, was seen. No tumours could be felt. The flap was replaced and the wound was dressed in the usual way. The patient stood the operation very well.

On Nov. 19th Mr. McGavin reopened the wound and the dura mater over the cerebellar area was removed. In doing this the lateral sinus was entered close to the middle line and the hæmorrhage was only stopped after the application of forceps. The cerebellum bulged extensively into the wound, but no tumour could be felt or seen. The patient lost a considerable amount of blood and a saline had to be administered per rectum. The wound was sutured and dressed, the forceps being left *in situ*, and the patient was sent back to bed. On the 20th salines, adrenalin, and calcium chloride were administered every four hours. The pulse was stronger, 112. The patient had been very restless and had tried to extract the forceps. On the 22nd Mr. McGavin, under chloroform, removed the forceps and plugging, but the hæmorrhage was so severe that they had to be replaced. The wound was dressed and was tightly bandaged. The patient became weaker but quieter, and the pulse was less rapid. On the evening of the 23rd the temperature went up to 102° F. and he became unconscious. The temperature continued to rise to 104°, and he died at 2.30 A.M. on the 24th with rapid obstructed breathing.

At the post-mortem examination a tumour was found on the right side which completely involved the auditory nerve and which extended right into the internal auditory meatus; the tumour was of about the size of a small cherry. On the left side a tumour of about the size of a chestnut was present which was pressing on the anterior part of the cerebellum, [illegible] 's side was only slightly involved [illegible] tretched out over the tumour. A [illegible] the falx cerebri.

[illegible] great interest, especially as the largest tumour was on the left side—that is, on the side on which the deafness was least marked. This is accounted for by the fact that the nerve had almost escaped on this side, whereas on the right side, where the deafness was almost complete, there was only a small tumour, but the nerve on this side was very extensively involved. The possibility of a second tumour on the left side never occurred to me, as I considered that the nerve deafness on that side was due purely to the increased intracranial tension which was evidently very great in this case. I think in this class of case careful testing of the ears before and after lumbar puncture would be of great value, as if only due to increased tension one might expect some improvement on the unaffected side, although should the condition on both sides remain the same, as it would have done in this case, then the question would arise as to whether there was a tumour on each side and whether the tension had been so great that the nerve had been *permanently affected, and in the absence of any other* symptoms pointing to a second tumour I am afraid the latter explanation in the present state of our knowledge would have to be accepted.

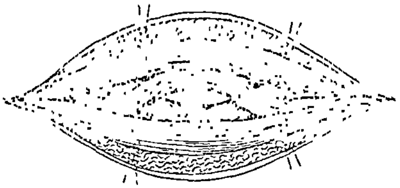
I am very much indebted to Mr. McGavin and Dr. Russell Wells for their great kindness in allowing me to publish this case, and to Mr. G. E. O. Williams and Mr. S. J. A. Beale for their very excellent notes of the case.

Harley-street, W.

A NEW METHOD FOR ATTEMPTING TO SECURE SPHINCTERIC CONTROL AFTER COLOSTOMY.

BY CHARLES RYALL, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

THE lack of sphincteric control is a great drawback to those who have to submit to a permanent colostomy. Many operations have been devised and carried out in order to get over this difficulty. Some of these have been found faulty and others are too complicated. The rectus abdominis is generally a well-developed muscle and remains fairly so in the majority of cases, until advanced emaciation is reached. Taking advantage of this fact, Howse performed colotomy by splitting the rectus vertically, and von Hacker carried out a similar procedure by splitting the fibres vertically and laterally and bringing the bowel through this oblique opening. This was performed with the hope of producing sphincteric control. The Maydl-Reclus operation of inguinal colotomy, where the layers of muscle were split and not divided, was an improvement on these as far as sphincteric control was concerned. All these operations were faulty, and this was in a great measure due to the spur operation being carried out and the difficulty of compressing and controlling the bulky spur. Since then Schinzinger, Braun, Weir, and others have dispensed with the spur by dividing the bowel, closing and dropping the lower segment into the abdomen, and trying to gain some sphincteric control over the upper segment by various operations more or less complicated. It is undoubtedly easier to control the upper segment alone than to attempt to do so with a spur. Recently Arbuthnot Lane has drawn attention to the advantage of drawing the upper segment through the rectus in those cases where the lower segment is either removed or else closed and dropped back into the abdomen. The rectus is a well-developed muscle and enables a good deal of control to be kept over a colostomy where the fibres are split vertically, but full advantage has not been taken of the value of this muscle as a means of making an artificial sphincter.



The method which I have resorted to appears to me to be original and is worthy of a trial. The rectus is split vertically and the sigmoid is drawn out and divided at a convenient point. The lower segment is closed and replaced in the abdomen. The upper segment is made less bulky by removing the appendices epiploicæ and freeing it of mesenteric fat, but without in any way interfering with its blood-supply. The artificial sphincter is then made in the following manner. A loop of muscle fibres is separated from the posterior aspect of the rectus on either side of the wound. Each loop is then drawn over to the opposite side of the wound, so that one loop overlaps the other. The overlapping loops thus form a ring and through this the bowel segment is drawn. Sutures are then inserted to keep the muscle fibres together above and below where the bowel comes through. Anchoring stitches are inserted through the skin and muscle inside to keep the bowel in position. The wound is then closed above and below the bowel and the cut edges of the latter are sutured to the skin. A double sphincter is thus formed consisting of longitudinal and circular fibres. The longitudinal fibres are those of the anterior portion of the rectus and the circular fibres are formed by the loops from the posterior part of the rectus. This operation can be modified by making double loops on each side and making them overlap one another alternately. A similar operation can be, and has been, carried out through the external oblique, and likewise can be done wherever the bowel is brought through muscle. A somewhat similar operation can also be performed for gastrostomy and appendicostomy.

Harley-street, W.

AN UNUSUAL CASE OF EXTRA-DURAL (PERI-SINUS) ABSCESS OF OTITIC ORIGIN AND ITS RELATION TO MELANCHOLIC STUPOR.

BY J. ARNOLD JONES, M.B., CH.B. VICT., F.R.C.S. EDIN.,
HONORARY ASSISTANT AURAL SURGEON TO THE MANCHESTER EYE AND EAR HOSPITAL.

ON Feb. 1st, 1908, I was summoned to see a woman of some 50 years of age, complaining of intense pain referred to the left ear, radiating over that side of the head, and of two or three days' duration. Since December, 1907, she had been under the care of mental physicians for melancholic stupor and had never had, to her own knowledge or to that of her family, any previous aural trouble. As a result of my examination a diagnosis of acute diffuse external otitis, probably following furunculosis, was made and the walls of the external canal were thoroughly incised. Before incision there was no visible discharge and no history of one, nor was there any constitutional disturbance, such as rise of temperature, &c. I saw her again in a week's time and the first thing that struck one was the marked improvement in her mental symptoms. Locally the pain had all disappeared and there was no tenderness, but there existed a copious discharge of pus. The walls of the external canal now admitted the introduction of an aural speculum, which disclosed to view a small polypoid granulation springing from the tympanum and filling the lumen of the canal, which was abnormally small. For some weeks the aural condition remained the same in spite of careful treatment, and the question of further operative interference then arose. The intensity of the otorrhœa suggested that more than the area of the tympanic cavity was involved and that the mastoid antrum and cells were affected; still, having regard to the short history of the attack, the complete subsidence of all acute symptoms, the alleged lack of previous trouble in the ear, and also to the absence of any other symptoms, I decided that conservative methods should be given a trial. Accordingly, on March 24th, under chloroform anæsthesia, I removed the tympanic polypus. The effect of this procedure was to increase the amount of discharge, which became so markedly out of proportion to the containing space of the middle ear that it was evident that carious processes were present in some other portion of the temporal bone. I therefore advised the performance of the radical mastoid operation. At this point it will be convenient to mention that the patient's mental symptoms had rapidly improved since the date of the first incision, and at the end of May, 1908, she was pronounced cured by her mental physicians.

On June 23rd I performed the radical mastoid operation which disclosed an interesting state of affairs. On the posterior wall of the osseous external meatus, situated about the centre of its long axis, was discovered the opening of a sinus The orifice of this sinus was about as large as the head of a good-sized pin, and upon tracing it backwards was found to lead through mastoid cells to the sigmoid groove. From this latter region about 1½ drachms of pus were evacuated, and the lateral sinus, itself normal, thoroughly exposed and cleansed. All cario-necrotic débris was removed from the antrum and cells which were thrown into one cavity by removal of "the bridge." There were no signs of caries of any portion of the labyrinthine capsule. The operation was completed in the usual fashion and an uneventful recovery under the care of her own medical attendant followed.

On August 1st I again saw the patient. The scar of the retro-auricular incision was hardly noticeable and the antro-tympanic cavity was lined with white shining epithelium, with the exception of a couple of small granulating patches posteriorly. On Oct. 2nd her own medical attendant examined the ear, and he wrote informing me that there was total absence of discharge, that the cavity was completely lined with epithelium, and that the patient's condition, both physical and mental, was excellent. I have just recently had news from him to the same effect.

There are many points of interest in this case, but the chief and overshadowing one seems to me to lie in the apparent relationship as cause and effect between the abscess and the mental symptoms of melancholia. A brief recapitulation of her mental attack will now be of service. The patient has had during her life several "nervous breakdowns." The earliest symptoms of definite melancholia were noticed in October, 1907, and consisted of depression and loss of sleep. These were followed by actual hallucinations, and late in December she was placed under the care of mental physicians. The diagnosis was that of melancholic stupor. On Jan. 17th, 1908, she became restless and agitated, and made many complaints of her physical condition for which there were no grounds. These symptoms became more marked until I first saw her on Feb. 1st, 1908, incised the walls of the external canal, and so established free drainage from the sinus in the osseous external meatus. From that date she quickly and steadily progressed to recovery, and late in May, 1908, was pronounced cured as regards the melancholia.

These are the definite facts of the case, and their interpretation is rather a matter for the mental physician than for an otologist. The local lesion may have been merely a concurrent event with the mental, but the sequence of cause and effect seems to me so striking as to justify the recording of the case. Here we have a lady with a certain amount of instability of the central nervous system described as "highly strung." Cario-necrotic processes of long standing are present in the temporal bone. An extra-dural abscess forms in the posterior fossa of the skull and melancholic symptoms occur. Then an acute exacerbation of the chronic mastoiditis takes place, the abscess tracks forwards, bursts through the posterior wall of the osseous external meatus, and sets up an external otitis. Drainage is established by incision, tension relieved, and the mental symptoms rapidly clear up.

A brief and necessarily imperfect reference to the literature of the subject discovers the following facts. Bianchi, translated by MacDonald in his standard text-book on "Psychiatry," sums up the whole situation when he says that "the pathological anatomy of melancholia is uncertain." Bernard Hollander[1] has collected about 50 cases, consisting of traumatic, inflammatory, and other lesions of the parietal area, and concludes from evidence adduced that a certain relation exists between the central area of the parietal lobe and melancholic states of mind. Two of his collected cases resemble my own, inasmuch as the melancholia was caused by brain abscess, the site of which, however, in both cases was the parietal lobe. Turner[2] demonstrated alterations of various degrees in the nerve cells and deduced arguments in support of the view that they were due to toxic impregnation of the nerve elements.

In my own case the site of the possible causative lesion differs from any I have found recorded. While others have discovered the parietal area to be at fault, in this instance the cerebellar region appeared to furnish the *fons et origo mali*. The explanation, however, must be left to those learned in mental physic, my own object having been accomplished in recording facts as I have observed them. *Ars medica tota in observationibus.*

A CASE OF ABSCESS OF THE PANCREAS.[1]

BY SETON S. PRINGLE, M.B. DUB., F.R.C.S. IREL.,
SURGEON TO MERCER'S HOSPITAL, DUBLIN.

THE subject of inflammatory disease of the pancreas has of late years excited great interest among not only surgeons but also among experimental and chemical pathologists, and as it is only by a careful study of the conditions present in a great number of cases that a true symptom-complex of this very interesting disease can be arrived at, I think that all cases met with should be reported, be the outcome successful or unsuccessful. It is only by the use of the knowledge thus gained that we can hope to arrive at a satisfactory method of treatment. The following is a short description of my case with the post-mortem findings, as it unfortunately belongs to the category of unsuccessful cases, and I regret that space will not permit me to discuss the etiology and treatment in general.

The patient, a man, aged 46 years, was admitted to Mercer's Hospital on June 26th, 1908, complaining of severe abdominal pain and gave the following account of himself. For the last 20 years he had been a very heavy drinker and for the past 12 months he had vomited almost every morning, and as a rule his breakfast had consisted of a glass of whisky. Otherwise he had always been healthy. On June 15th the patient was seized with severe colicky pains in the left abdomen, chiefly in the region of the umbilicus; there was also some tenderness in the upper abdomen, but he said that the abdominal wall was quite soft though slightly distended. As his bowels had not moved for several days he took a purgative and was very considerably better on the following day, the 16th. From this until the 21st of the month he suffered constant pain in the abdomen but not of a severe character; the bowels remained constipated. On the 21st (i.e., the seventh day of the illness) he noticed that the pain had settled in the right side of the upper abdomen between the umbilicus and costal margin and that the abdominal wall was rigid. Diarrhœa also set in on that day and had persisted. The motions were yellow in colour and of a semi-fluid, pasty character. On the following days the pain gradually grew worse, but he was able to attend to his business until June 26th (twelfth day of the illness), when he was suddenly seized with acute pain and went immediately to the hospital, whither he was able to walk. He had vomited occasionally since the attack began, but at no time was it a marked feature and had not occurred for the last few days.

On my arrival at the hospital about an hour after the onset of the acute pain I found the patient lying on his back with his legs drawn up, sweating profusely. His face was flushed and anxious; his respirations were rapid, 30 a minute, and entirely thoracic; he evidently found it difficult to talk on account of the abdominal pain, and spoke in a jerky manner. His temperature was 98° F., his pulse was 100, and his tongue was dry and dirty; there was no jaundice. I found his abdomen distended and the whole abdominal wall absolutely rigid. He pointed to the right epigastrium as the seat of the pain, which also radiated down to the right iliac fossa and was apparently very severe. There was considerable tenderness in the umbilical and epigastric regions; percussion revealed a dull note over the upper two-thirds of the abdomen, the dulness extending into the flanks. I could not demonstrate the presence of free fluid in the abdominal cavity. As there was evidently peritonitis present I decided to operate at once, although a definite diagnosis as to the primary lesion was impossible. I suggested the possibility of a chronic duodenal ulcer which had perforated into a mass of adhesions on the 15th and that now the infection had spread through the limiting adhesions and was causing the acute peritonitis.

Operation.—As soon as the muscles relaxed under the influence of the anæsthetic I could feel a more or less rounded mass occupying the whole of the upper abdomen, the centre of the mass lying an inch or so above the umbilicus. After the usual preparations I opened the abdomen by a four-inch incision in the mid-line above the umbilicus. I then immediately saw that the tumour which I had palpated consisted of the pyloric part of stomach, duodenum, transverse colon, and some coils of small intestine all matted together, while the great omentum was turned up over the mass thus formed and was adherent to the under surface of the liver. The diagnosis also at once became evident, as typical patches of fat necrosis could be seen dotted over the great omentum, and I thus knew that I was dealing with a case of acute pancreatitis with probably abscess formation. There was a small quantity of blood-stained fluid in the peritoneal cavity. The great omentum was easily separated from the liver and turned down and I then saw a quantity of fresh fibrin gluing a coil of small intestine to the lower margin of the transverse colon. On separating the adherent coils at this point I opened directly into a large cavity full of brownish grey odourless pus streaked with blood. I at once plugged this opening with gauze without allowing any soiling of the general peritoneal cavity to take place and then sutured the edges of the parietal peritoneum to the coils of intestine around the opening into the abscess which was thus made to empty directly into the abdominal wall. The rest of the wound in the parietes was then sutured except at the upper angle, through which I inserted a wick of gauze leading down to the neighbourhood of the foramen of Winslow, where I had noticed a quantity of fresh fibrin. I then [illegible] the abscess and subst [illegible] voluminous dressing, [illegible]

Progress of the case.—The patient rallied well after the operation, and next morning he was free from pain with a normal temperature and pulse of only 112. There was a free discharge of the grumous material from the tube, the distension was less, and his general appearance very good. [illegible] took fluid nourishment [illegible]. I was rather pleased [illegible] y the condition continued good, but as there had been no movement of the bowels I ordered him that night a dose of castor oil. The next day he had nine semi-fluid pasty motions of a yellow colour. On the fifth day he vomited once a brownish fluid and was distinctly weaker. On the sixth he vomited several times and a hiccough also developed, so that I ordered his stomach to be washed out. From this time till his death on the twelfth day after operation the vomiting and hiccough continued. The latter was particularly irritating and proved uncontrollable, although his stomach was frequently washed out, and many drugs were tried. He gradually lost strength and was unconscious for some hours before death.

The character of the discharge changed completely in a few days after operation, and by the fifth day a great quantity of an almost clear viscid fluid was being poured forth. This secretion digested the abdominal wall round the wound, causing the latter to open to a large extent; this discharge continued to the end. There was a trace of albumin in the urine on the day of admission, but at no time could sugar be detected; a marked Cammidge "C reaction" was, however, obtained on the third day after operation. The course of the fever was irregular until the eighth day after operation, rising at times to 102°, and then remained normal till death. The pulse was as high as 150 on the sixth day and then gradually fell to the neighbourhood of 120 on the day of his death, the twelfth day after operation.

Post-mortem examination.—Unfortunately, permission for a full necropsy could not be obtained, and a hurried examination had to be made through the operation wound. On enlarging the opening through which the drainage tube had led into the lesser sac it was found that the head and body of the pancreas were represented by several dirty grey sloughs, while completely separated from these lay the tail of the gland. This was easily removed, but in doing so a second abscess cavity lying in the left loin was evidently opened into, from which escaped several ounces of brown, grumous material similar to that evacuated at the operation. No trace of the pancreatic duct could be discovered extending from the tail to the duodenum. There were no gall-stones present and no evident cholangitis. The stomach and duodenum showed marked evidence of catarrhal inflammation. There was no diffuse peritonitis. The specimens removed were handed to Dr. W. G. Harvey, who reports as follows: "The specimens consist of (*a*) a portion of the pancreas about four inches long, apparently the tail of that organ. This presents a fairly normal appearance to the naked eye, but on cutting into it a considerable amount of congestion becomes apparent, and many small areas of fat necrosis are seen scattered through it. (*b*) Several large pieces of slough resembling 'wash leather.' The surface of the end of the piece of pancreas which would lie towards the right in the body is rough and rather irregular in outline and evidently represents the line of separation of the slough from the surviving pancreas. Microscopically sections of the former portion show, on the whole, a remarkably healthy appearance. The glandular tissue stains well, but there is much congestion, a very considerable increase of connective tissue, and a marked thickening of the vessels. Sections through the extreme right end of this part, i.e., through the 'line of demarcation' show on the surface a narrow zone of necrosis, while under this the connective tissue appears more affected than the epithelial, strands of necrotic fibrous tissue passing some distance in between healthy gland substance. Here and there in these sections are seen localised areas of necrosis of the gland sharply marked off from the healthy tissue. The ducts show a severe catarrh. The fat in parts appears normally as clear spaces, but in parts many fat cells contain crystalline and amorphous deposits. Sections of the sloughs show a deep pigmentation of such few glandular elements as are still recognisable. The remainder is a homogeneous necrotic mass traversed by a few pink lines of connective tissue such as one sees in caseating gummata."

---

[1] Abstract from a paper on Abscess of the Pancreas read before the Surgical Section of the Royal Academy of Medicine in Ireland on Jan. 8th, 1909.

In a review of the literature Mayo Robson[2] has been able to find reports up to 1907 of only 14 operations for abscess of the pancreas, with five deaths. Since then, however, Brewer[3] reports two successful cases of drainage for circumscribed pancreatic abscess. I regret that in this case I did not make a counter opening in the back at the left costovertebral angle and so drain the collection of pus which was discovered post mortem, although I do not see that a favourable outcome could have been expected considering the extent of the gangrene and the fact that all connexion between the surviving tail of the pancreas and the duodenum had been severed.

Dublin.

FOUR CASES OF CHRONIC MIDDLE-EAR SUPPURATION WITH INVOLVEMENT OF THE LABYRINTH.

BY MACLEOD YEARSLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL EAR HOSPITAL; MEDICAL INSPECTOR OF LONDON COUNTY COUNCIL DEAF SCHOOLS, ETC.

THE following four cases, which have occurred in my practice at the Royal Ear Hospital during the past 18 months, are all of considerable interest.

CASE 1.—The patient, aged 13 years, a scholar at the London County Council Residential Deaf School for Girls, had been deaf from double middle-ear suppuration, following scarlet fever at the age of three and a half years. The right ear showed a large perforation with a polypus protruding. On the left side the membrane was almost entirely destroyed and pus was coming from the attic. On Jan. 23rd, 1908, the radical mastoid operation was performed on the left ear. There was caries of the long process of the incus, and of the malleus only the head remained. The attic and aditus were filled by granulations. The polypus in the right ear was removed at the same time. The patient did well until the 25th, when the evening temperature rose to 100·2° F., falling the following morning to 98°; in the evening it rose to 100·6°, reaching normal on Jan. 27th, when the left ear was first dressed. On the 30th she was better in every way. That afternoon the radical mastoid operation was performed on the right side. No ossicles were found, the antrum was full of pus and granulations, and the tegmen antri was carious. On the 31st she was drowsy and vomited most of the day, the temperature rising until 6 P.M., when it reached 103·8°. There was a definite rigor at 2 P.M. She lay in a curled-up position, the knee-jerks were absent, but there was no rigidity and Kernig's sign was absent. There was distinct right lateral nystagmus. The dressings were removed and a drainage-tube was put into the antrum through the external meatus. Calomel, gr. v., and antipyrin, gr. x., were given. At 10 A.M. on Feb. 1st the wound was reopened and more bone removed. The dura mater was bulging and non-pulsatile; on opening, about half an ounce of clear fluid escaped. The brain was explored without result and the wound was redressed. The temperature fell to normal and by 4.30 P.M. the patient was more comfortable. Right lateral nystagmus persisted. She became worse at 6 P.M.; the temperature was 101·6°, the pulse was 96, and the respirations were 24, reaching 104·2°, 100, and 24 respectively at 8 P.M., when she had a rigor. She was sponged and given gr. ⅛ of morphia at 9.30 P.M. She became very noisy, talking and singing nursery rhymes all night. At 1 A.M. she began to pass everything under her. At 10.30 A.M. on Feb. 2nd the temperature was 101°, the pulse 96, and the respirations 24; she was again anæsthetised and a small cerebral hernia through the tegmen antri was removed. The brain was again explored and, during this exploration, the lateral ventricle was tapped, about two ounces of very foul, coffee-coloured fluid being evacuated. She died at 6 P.M. on Feb. 3rd, the temperature reaching normal and the pulse 88 after the last operation and rising to 103·4° and 146 just before death.

In deference to the wishes of the parent, the head only was examined by Mr. W. H. Bowen. Suppurative meningitis, due to infection spreading through the labyrinth, was found. There was an erosion through the superior semicircular canal with a corresponding perforation of the dura mater. In his report Mr. Bowen stated that "without a thorough clearing out of all the internal ear the disease could not have all been removed and even for this to be successful the operation should have been done months before." The stapes was intact and there were no signs of any lesion of the labyrinth at the time of operation. The lateral sinus and posterior fossa were intact.

CASE 2.—The patient, a boy, aged nine years, a scholar at the London County Council Deaf Centre at Somerford-street, Bethnal Green, suffered from discharge following measles in infancy. The left ear showed complete destruction of the tympanic membrane, the upper part of the tympanum being occupied by cholesteatomata, the lower part by granulations. On the right side the whole tympanum was full of granulations. Both ears discharged very foul sanious pus. The tonsils were hypertrophied and there was a large mass of adenoids. The boy had only vowel hearing on both sides. There was no nystagmus and Romberg's sign was absent. Coördinated movements were performed without any hesitation. On Feb. 6th, 1908, the right radical mastoid operation was performed. On clearing the antrum, aditus, and tympanum of much foul pus, débris, and granulations, it was found that there was a fistula into the external semicircular canal, the stapes was absent, and the margin of the fenestra ovalis was carious. The vestibule was opened by enlarging the oval window inferiorly, and the cavity was swabbed out with hydrogen peroxide and then with pure formalin. The operation was completed in the usual way, packing being done *viâ* the meatus.

The boy made an uninterrupted recovery, but had twitchings of the facial muscles lasting about two days after the operation. A left radical mastoid operation was performed on Feb. 9th, and a few days later both tonsils were enucleated and a large mass of adenoids removed. Functional testing on Jan. 21st, 1909, gave the following result: The bell was not heard by either ear; the open vowel "a" was heard on the left side when spoken very loudly close to the ear; Weber's test was lateralised to the left, and to the C 128 fork some bone conduction, but not reliably estimable, was present; that fork on the right mastoid was referred to the left. By air conduction no fork was heard by either ear.

CASE 3.—The patient, a female, aged 22 years, sent by Dr. C. C. Gibbes, had suffered from double otorrhœa on and off since measles in childhood. Since July, 1907, the discharge from the right ear had been very offensive and sanious. About the middle of September, 1907, she had an attack which was described as "inflammation of the brain"; she was attending a meeting and fell forward suddenly from her chair and was carried home unconscious. Until December she was very ill, but no clear details of her symptoms were obtainable, save that vertigo, vomiting, and tinnitus "like being in a railway station" were prominent. The only information as to the form of her vertigo, was that in March, 1907, she had a sudden attack which caused her to fall towards the right. When seen on April 29th, 1908, she was obviously ill. The left ear was discharging slightly, the lower part of the membrane was destroyed, and the malleus hung free. The right meatus was full of very foul pus, stained with blood, and on cleansing large polypoidal masses blocked the inner end. She heard well on the left side, but was apparently quite deaf on the right. She was, however, too ill to be tested. There was no nystagmus, the temperature was 98° F., and the pulse 100. She was at once admitted, and next morning the temperature and pulse were 97° and 80.

---

[2] Mayo Robson and Cammidge: The Pancreas, its Surgery and Pathology, 1907.

[3] Brewer: Surgery, Gynæcology, and Obstetrics, September, 1907.

On April 30th a radical mastoid operation was performed. On reaching the antrum very offensive curdy pus was found, and, as the opening was being enlarged, it escaped as if it were being pumped out. On removing the bridge and clearing the antrum and attic of much granulation tissue it was found that the inner antral and tympanic walls were occupied by a bed of soft granulation tissue, across which the facial nerve lay exposed. No ossicles, either malleus, incus, or stapes, were found. Loose sequestra were felt and removed, great care being exercised to prevent injuring the nerve. Two large ones and two small ones came away easily. The former comprised a part of the vestibule, with the openings of the semicircular canals, and a much eroded portion of the promontory. Under the latter was found a small piece of the modiolus and lamina spiralis ossea. The condition of the patient being such as to render it inadvisable to complete the operation, the wound was lightly packed from the incision, and a few days later a flap was fashioned, the incision sutured, and the operation finished in the usual way. The patient has made an uninterrupted recovery, but as the exposed facial nerve became surrounded with organising tissue, facial paralysis appeared and gradually became worse.

Case 4.—A girl, aged 12 years, was sent to me on Jan. 13th, 1909, by Mr. H. L. E. Wilks of Salisbury, with a note to say she had been under his care at the Salisbury Infirmary "with an acute mastoid one year ago." He had operated and removed some carious bone and established a communication with the middle-ear. The acute symptoms had subsided, but there had lately been a purulent discharge from the external meatus. I have, I regret to say, been unable to obtain any further information as to the original condition of the child from Mr. Wilks. On examination there was found a profuse, offensive, watery discharge from the right ear, the meatus of which was stenosed. The membrane was destroyed except Shrapnell's portion, the inner tympanic wall covered with fine granulations. There was tenderness over the antrum. The temperature was 100° F. and the pulse was 102. No nystagmus could be elicited by the caloric test and no history of giddiness could be obtained.

On Jan. 15th, 1909, a radical mastoid operation was performed, the incision passing through the scar left by the former operation. No sign of the latter could be found in the bone, save a small pit just behind the spine of Henle. Both antrum and aditus were large and full of granulations The head of the malleus was found, but both incus and stapes had disappeared. A fistula over the prominence of the external semicircular canal, large enough to admit easily a probe, was seen, and the latter instrument, given a suitable curve, passed into the tympanum through the vacant oval wi[illegible] Case 2 —viz., [illegible] low the oval wi[illegible] ollowed by formalin. The case has progressed without any unfavourable symptoms. On functional testing (Feb. 15th, 1909) she apparently heard well in the right (operated) ear, but on using Bárány's noise-producing apparatus to the left ear it was clearly demonstrated that this hearing was entirely supposititious.

Each of these cases is of considerable interest. In the first there were no symptoms specially leading one to suspect the presence of any grave labyrinthine condition on the right side, and had that ear been opened up first it is questionable from the condition found post mortem whether she could have been saved. There were, however, no guiding symptoms to lead to a decision as to which was the worse ear. It is extremely probable that the removal of the polypus lead to a lighting-up of the labyrinthine condition and consequent meningeal infection. Several years ago I had under my care a woman, aged between 40 and 50 years, in whom both ears were filled with granulations. As the mastoid operation was refused absolutely I curetted both ears (the only operation to which she and her friends would consent) and she succumbed to suppurative meningitis three days later. The infection was found to have reached the meninges *viâ* one labyrinth. This case was probably similar to that of Case 1. I would point out the difficulty of obtaining reliable information from deaf-mutes or their relatives which would lead to a suspicion of the true condition. The lesion found in Case 1—viz., erosion of the superior semicircular canal—is decidedly uncommon. I regret that no tests were made as to the condition of the labyrinthine function, but at the time I saw this case I was unacquainted with the work of Bárány and others.

The history of Case 3 showed that this patient was attacked by acute labyrinthine suppuration during chronic purulent middle-ear disease, and it is interesting as showing to what extent such a condition may pass without causing intracranial complications. There are several cases on record in which complete necrosis of the labyrinth has taken place, notably that by Hugh E. Jones[1] of Liverpool. The ensuing facial paralysis was regrettable but unavoidable under the circumstances; it did not appear until the nerve became pressed upon by the new-formed cicatricial tissue. I have proposed a grafting operation to the patient, but this she refuses.

Cases 2 and 4 are very similar. In both there was erosion of the external semicircular canal, with loss of the stapes; in neither was the condition suspected before operation was undertaken. The method followed—viz., opening the vestibule by removing the outer wall below the fenestra ovalis (to which the term "inferior vestibulotomy" has been applied)—appears to me to be the best way of dealing with such cases; it ensures drainage at the lowest part of the vestibule and is in full communication with the canals (as shown by the bubbling of the peroxide of hydrogen through the erosion in the external canal), and is well away from the facial nerve. There is no need, in my opinion, to enlarge the fistula into the canal (so-called "superior vestibulotomy"), as the lower opening gives all the necessary drainage and to do so would endanger the nerve. It is possible that both these cases might have done perfectly well had the vestibule been left untouched, but considering the usual surroundings of the individual patients it was unwise to take the risk.

Case 4 further opens up an interesting point—that of hearing when the stapes has been lost or the labyrinth damaged. Owing to the relatively badly developed sense of sound direction in man, coupled possibly with hearing by bone conduction, such patients often appear to hear quite well with the damaged ear, even when the good ear is carefully sealed. In such cases Bárány's noise-producing apparatus becomes a valuable instrument and is the only method by which reliable evidence as to the true hearing can be obtained.

Harley-street, W.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Red Degeneration of a Uterine Fibroid.—Unusual Solid Tumour of the Ovary.—Fœtal Chondro-dystrophia.—Primary Chorion-epithelioma of the Ovary.—Rudimentary Uterus Didelphys.

A MEETING of this section was held on June 10th, Dr. HERBERT R. SPENCER, the President, being in the chair.

A short communication was read by Mr. J. BLAND-SUTTON on Red Degeneration of a Uterine Fibroid associated with staphylococcus pyogenes aureus infection.

Mr. G. F. DARWALL SMITH read a short communication on an Unusual Solid Tumour of the Ovary. The patient from whom the tumour was removed was a multiparous woman, aged 36 years. She was found to have a rounded, solid tumour in the right posterior quarter of the pelvis of the size of a man's fist. This was removed, and on examination the tissue of the ovary could be seen to be stretched as a capsule over the substance of the tumour proper. The cut surface of the tumour looked like an ovarian fibroma. On microscopical examination, scattered about in the fibrous stroma were seen strands of cells resembling glandular epithelium. Some of these cells showed degenerative changes. The diagnosis seemed to lie between endothelioma and adenofibroma.—Dr. W. S. A. GRIFFITH mentioned that he had removed a similar tumour of the right ovary with similar microscopical characters. The tumour showed clinically no signs of malignancy.

A short communication by Dr. KEDARNATH DAS on Fœtal Chondro-dystrophia as a cause of brow presentation and dystocia was read, and notes of two cases of this condition were given.

Dr. J. S. FAIRBAIRN read a paper on Primary Chorion-epithelioma of the Ovary. The paper was based on the case of a woman who had had four pregnancies, the last in February, 1905, when the placenta was removed by hand and the convalescence was protracted. For some months before admission to St. Thomas's Hospital there had been slight, but continuous, uterine hæmorrhage, and for about six weeks abdominal pain, chiefly on the right side. A tender swelling in the abdomen had been noticed by the patient for about three weeks and was the reason for her seeking advice. This was thought on examination to be an ovarian cyst with torsion of the pedicle, but at the operation on Jan. 3rd, 1907, it was found to be a hæmorrhagic tumour of the left ovary with extensive adhesions, but no twisting of the pedicle. It was removed and also the right ovary, which was cystic and involved in adhesions. The patient showed no signs of recurrence two years after operation. Other cases of primary chorion-epithelioma in the ovary were discussed. Seven collected by Pick, and others by Michel, Schmaus, and Kleinhans were mentioned, but particular attention was directed to two from Doederlein's klinik which occurred in multiparæ, and appeared to be very similar to the one described. Three possible explanations of the origin of chorion-epithelioma primary in the ovary offer themselves: (1) It may arise, as in Pick's cases and as in chorion-epithelioma of the testicle, from teratomatous elements; (2) it may arise from a preceding ovarian pregnancy; and (3) it may be due to transportation of villi from a preceding pregnancy, molar or otherwise. The present case and Doederlein's two were considered as in a class by themselves and as differing from Pick's in that his series included many younger patients (ages 9, 16, 17, 21, 24, 30, and 36), that all except one were nulliparæ, and that there was more definite evidence of a teratomatous origin in the mixed nature of the tumour elements and in the extreme malignancy of the growths. Any further discussion as to the origin of such primary growths must be purely speculative, but as suggesting a possible origin from transported villi attention was directed to the fact that in two of the three cases specially considered it was found necessary to remove the placenta manually in the labour immediately preceding the illness.

Dr. W. BLAIR BELL read a paper on a case of Rudimentary Uterus Didelphys with ectopia of each uterine body in an inguinal hernia sac, with some remarks on the development of the female genital organs. The patient was a young woman, aged 20 years, who had had a double inguinal hernia all her life. Lately there had been attacks of abdominal pain, which caused her to seek advice. The patient was found to be well developed and intelligent. She had never suffered from monthly molimina. The external genitals were normal in appearance and covered with hair. There was total absence of the vagina, but a circular fringe indicated the formation of a hymen. Per rectum no pelvic genital organs could be detected. At the operation a central sub-umbilical incision was first made in order to investigate the state of affairs. There was a smooth and uninterrupted vesico-rectal pouch. Above the true pelvis on either side there was a large hernial orifice. Protruding down the right aperture was the Fallopian tube and ovary; on the left side only the fimbriated extremity of the tube was visible. An incision was next made over the left inguinal canal, and the hernial sac—together with the left uterine body, which was firmly incorporated with it, and the Fallopian tube and ovary—was removed, and a radical cure effected. On the right side the hernial sac and the uterine body were separated from the Fallopian tube and ovary and removed, a radical cure of the hernia being then carried out. The patient made an uninterrupted recovery. On histological examination the left ovary was found to be functional. The conditions of uterus didelphys and hernia of the uterus were discussed and their relative importance considered. The rarity of actual ectopia of uterine bodies, such as was found in the case described, was mentioned, the only other similar cases on record being those of Roux and Werth. Finally, the "descent" and development of the genital organs was considered in so far as the malformation found in this and other cases seen and mentioned by Dr. Bell were concerned.

OPHTHALMOLOGICAL SOCIETY.

Congenital Displacement of Lenses.—Congenital Opacities of Lenses.—Retinal Disease with Massive Exudation and Arterio-venous Communication.—Epithelial Filament simulating a Threadworm in Anterior Chamber of the Eye.—Report of International Committee on Unification of Notation of Visual Acuity and of Meridians of Astigmatism.—Exhibition of Cases.

A MEETING of this society was held on June 10th, Mr W. H. H. JESSOP being in the chair.

Mr. P. E. H. ADAMS read two papers, the first on a family with Congenital Displacement of Lenses. The series consisted of a mother and seven out of her nine children who suffered from this condition, but no other instance could be found in the family. In three of the cases the lenses were displaced downwards instead of the more usual displacement upwards, while in the eldest boy the dislocation was complete, thus leaving the pupil clear of the lens. The two members of the family who were unaffected had perfectly normal eyes. The second paper was on a family with Congenital Opacities of Lenses. In this family the great-grandfathers, grandmother, father, and four of his children (out of five), as well as the father's sister, showed the peculiar opacities of the lens known as stellar cataract. Posteriorly there were from three to eight primary rays and numerous secondary ones, while some of them showed Y-shaped markings on the anterior surface as well. The opacities slowly increased throughout life, especially in the front of the lens, while the posterior markings were broader and less defined.

Dr. A. HILL GRIFFITH and Mr. A. W. ORMOND communicated a paper entitled, "A Case of Retinal Disease with Massive Exudation and Arterio-venous Communication." The patient was a female, aged 31 years. The left eye had been removed for secondary glaucoma by Dr. Griffith ten years ago. The fundus of the remaining eye showed very tortuous and distended retinal vessels, with varicosity of several of them and a red blurred optic disc. In the extreme periphery of the fundus, deep to the retinal vessels was a whitish mass, the limits of which could not be seen. Issuing from the anterior border was a large vein and running to it an artery somewhat similar in size and colour. The changes in the fundus were probably all due to vascular disease. The interest in the case was furthered by the fact that the other eye of the patient was removed for secondary glaucoma simulating an intra-ocular growth, and on examination it proved to be a case of extensive sub-retinal exudation with retinal detachment and an old organising hæmorrhage, but no growth. The patient's sister also lost an eye from a similar cause and the same condition was found on pathological examination.

Dr. **George Mackay** reported a very unusual appearance, an Epithelial Filament simulating a Threadworm in the Anterior Chamber of the Eye of a girl, aged seven years. The child had always enjoyed good health, had no special illness, had never suffered from worms, and had not complained much about the eye. The filament had been first noticed when she was eight months old. No independent movement had ever been detected in it, but the parents were under the impression that it was slowly increasing in size. The eye was occasionally a little irritable, with a tendency to lacrymation, and a trace of ciliary injection. The tension was normal, the media otherwise transparent, and the fundus healthy. The pupil responded to light, though less mobile below than above. At the periphery of the iris, close to the anterior chamber angle, between the 5 and 6 o'clock meridians, a buffy-grey filament about a millimetre in diameter emerged between the fibres of the iris, ascended in close relation to the posterior aspect of the cornea for 3 or 4 millimetres, then bent backwards towards the lower border of the pupil, and crossing the vertical meridian of the anterior chamber appeared to rest lightly in contact with the sphincter surface of the iris. Thereafter it bent downwards once more, following the plane of the iris nearly in the 7 o'clock meridian. The structure terminated in a slightly bulbous free extremity which did not re-enter the iris nor extend to the angle of the anterior chamber. The arched filament had thus a slight spiral twist from before backwards. The refraction of the eyes was about emmetropic. The vision of the right eye $\frac{6}{12}$ fairly, and the left $\frac{6}{6}$. The child was put under chloroform, and through an incision made at the corneo-scleral junction, a little to the nasal side of the filament, the foreign body was successfully removed, though breaking into two pieces on account of its brittle structure. From the pathological examination made by Dr. Theodore Shennan of Edinburgh and Mr. A. E. Shipley of Cambridge no confirmation was obtained of the presence of a parasite. Microscopic sections showed that the filament was mainly composed of stratified epithelium, with a little loose connective tissue and some melanine pigment. Discussion was invited as to its probable origin—e.g., in a congenital displacement of part of the epithelium from the anterior surface of the iris or a capsulo-pupillary vestige.

Mr. **Jessop** gave a report of the International Committee on the Unification of the Notation of Visual Acuity and of the Meridians of Astigmatism. The committee, after consideration, came to the following conclusions:—1. That the meridians of astigmatism should be measured and represented as the observer looked at the patient. 2. That the axes should be measured and represented in the lower semi-circle of the trial frame. The numbering of the axes should start from the middle line of the face in each eye, and proceed downwards and temporalwards. The zero would therefore lie at the nasal end of the semicircle and 180° at the temporal end; 90° would be below and midway between these points. The committee also agreed that for international test type numbers should be used. Landolt's ring was also thought to be a suitable object. The unit of measure was an angle of 1 minute, and the figures were to be constructed on this unit. The types were to be constructed as regards size on arithmetical progression, and the standard distance at which they were to be seen should be 5 metres. The source of light was to be diffuse daylight, if possible, opposite the types, and not laterally.

The following cases were shown:—

Dr. **A. Freeland Fergus**: A case operated upon for Paralytic Ptosis by his method of resection.

Mr. **J. Herbert Fisher**: An Unusual Form of Cataracts (Bilateral) in a girl.

Mr. **Jessop**: A case of Bilateral Ptosis with complete Ophthalmoplegia Externa.

Mr. **W. M. Bergin**: A case with a Unilateral Swelling.

Mr. **C. S. Blair**: A case of Pemphigus of the Conjunctiva.

Mr. **Herbert Bell**: A case of Unusual Elastic Adhesion between the Iris and the Cornea.

Mr. **Arnold Lawson**: (1) A case of Double Iridectomy for Congenital Glaucoma by the method of Lagrange; and (2) a case of Congenital Glaucoma treated by Langrange's iridectomy.—This case was discussed by Dr. **Weeks** (Philadelphia), Mr. **G. T. Brooksbank James**, Mr. **E. Treacher Collins**, Mr. **Odillo Maher**, and Mr. **F. R. Cross**.

Medico-Legal Society.—A meeting of this society was held on June 22nd, Dr. James Scott being in the chair.—Mr. H. Wippell Gadd read a paper on the Poisons and Pharmacy Act, 1908, in Relation to Public Health and Safety. The speaker criticised the Act in detail, drawing particular attention to Section 2, which empowers persons other than qualified chemists and medical men to sell certain poisons. Mr. Gadd showed how inconsistently the Act had been interpreted by the local authorities empowered to grant licences to unqualified applicants.—Dr. S. B. Atkinson, Dr. Hubert Biss, Mr. R. A. Robinson, Mr. W. C. Williams, and Dr. Scott joined in the discussion.—Mr. Roland Burrows, LL.D., read a paper on the Law of Exhumation. The law relating to the disposition of the dead was, he said, most unsatisfactory. A curious duality ran through it which alone tended to cause confusion. Exhumation was so unusual that comparatively few people had any knowledge of the law relating to it. The motives actuating civilise nations in disposing of their dead—religion, reverence and public health—were not necessarily consistent. All c them had had influence on the law. Nowadays public healt appeared to be the dominating influence. Until 750 A.D., whe Archbishop Cuthbert introduced the custom of churchyar burial, burial in or near a church was only accorded to person of special sanctity. Even then it was not until after the Reformation that the exaction of burial fees by clergyme ceased to be regarded as an offence against the law of God The custom of churchyard burial, however, though general was never a binding rule. Neither the canon nor the commo law required the body to be placed in a coffin; nor was ther any rule as to the material of which the coffin was to be constructed. The duty of burial as imposed by the law was t convey the body decently covered and in a reverent manne to a place of sepulture and, in like manner, to bury it. Tha duty rested on the person having control over the body *Prima facie*, it was the executor or administrator; but th relatives, and even the householder under whose roof th body lay, incurred the obligation. The only excuse wa poverty. The duty, however, was overridden by the paramount duty not to do anything to avoid an inquest or t conceal a crime. The deceased had no power to regulat the place or manner of his burial except that he might forbi cremation and had certain powers to devote his body fo anatomical study under the Anatomy Act, 1835. Exhumation might lawfully take place under a faculty an a licence other than under the law of inquests. I five case it could take place: (1) the investigation o the cause of death of the person buried; (2) when th land was devoted to other uses; (3) under the Burial Acts for the protection of the public health; (4) to give effect t the wishes of the deceased or relatives as to the place o burial; and (5) incidentally, for purposes not directl relating to the cause of death. Mr. Burrows supported hi paper with numerous decided cases, and also referred t instances where opposition had been made to exhumatio orders. In conclusion, he urged that the law on the subjec stood in urgent need of reform.—Discussion followed, in which Lord Russell, Dr. Atkinson, and Dr. Scott spoke.

The New Vaccination Law in Burma.—The Burma Vaccination Law Amendment, 1909 (Burma Act 1 of 1909), was brought into force on May 24th, 1909. Section 9 of the Act, which gives power to require persons on board vessels on arrival at the port of Rangoon (who have travelled on board such vessel for the purpose of coming to Burma to work as labourers) to be inspected, and if found unprotected to be vaccinated, will until further notice be put into force in respect of vessels arriving from Calcutta only.

Reviews and Notices of Books.

Report on the Prevention of Malaria in Mauritius. By RONALD ROSS, C.B., F.R.S., D.Sc., LL.D., &c., Professor of Tropical Medicine in the University of Liverpool and the Liverpool School of Tropical Medicine. London: J. & A. Churchill. 1908. Pp. 202, with 25 photographs and a map. Price 5s. net.

AT the request of the Governor of Mauritius, conveyed through His Majesty's Secretary of State for the Colonies, Professor Ronald Ross visited Mauritius in 1907 with a view to advise measures for the prevention of malaria, the disease having shown of late years a tendency to increase, no fewer than 5827 deaths having been ascribed to that cause during 1906. He remained three months in the island collecting information and investigating the local conditions associated with the malady. This report, as might have been expected, is a most valuable and exhaustive work, treating the whole subject from all points of view. Before discussing the circumstances of malaria in Mauritius the author sets out in simple terms, mainly for the benefit of non-medical readers, a summary of modern views respecting the malady. There is also a historical account of the behaviour of the disease in Mauritius, and from it we learn that Professor Ross is of opinion that in all likelihood malaria was not endemic in the colony before 1865. The particular mosquito responsible for transmitting the malady in Mauritius is the Pyretophorus costalis, which was probably brought to the island by some ship. With the importation of Indian coolies to labour in the sugar plantations infected persons arrived in considerable numbers. So that with local conditions favouring the multiplication of the mosquito, and with a supply of infected persons whose blood contained the parasites of the disease, malaria rapidly extended in the colony, giving rise in 1866 and 1867 to the terrible epidemic which carried off in 1868 alone no less than one-fifth of the entire population, leading some persons to take the view that the disease in question was not malarial fever at all, but plague or cholera, so great was its virulence. Professor Ross in his recent inquiry adopted as his index of malarial prevalence the number of children under 16 years suffering from enlarged spleen; and he points out that malaria will not remain in a locality unless the carrying agent, the anophelines, are numerous, unless there are enough infected persons to infect the carriers, and if the insects are prevented from biting human beings.

Keeping this in view, Professor Ross summarises preventive measures under the following headings: anopheline reduction, case reduction, and isolation. As regards anopheline reduction, he points out the value of drainage in removing surface waters, which favour the breeding of the insects. In respect of case reduction he urges the continued use of quinine, which removes, or, at least, diminishes, the number of available parasites in the blood. And as regards isolation, or protection from mosquito bites, he discusses the protection to be derived from culicifuges, such as oil of lavender applied to the skin; the use of mosquito nets, especially at night; the wire-gauze screening of windows and verandahs where practicable; and the covering up of the exposed skin by veils and gloves. He places the greatest importance upon reduction of mosquitoes, which can be attained either by major works of drainage of marshes and clearing out of overgrown watercourses, or by minor works which comprise the systematic searching out of smaller breeding grounds of the mosquitoes, the filling up of pools or hollows, and general attention to the sanitary surroundings of the people. He quotes instances where malaria preventive measures have been successfully carried out, as, for example, at Ismailia, the Federated Malay States, Hong-Kong, and the Panama Canal zone. Finally, he recommends that in Mauritius a periodical spleen census of children in schools and on estates should be taken to note the number with enlargement of that organ; treatment by quinine of all children suffering from enlarged spleen; continuous house-to-house distribution of quinine when necessary; house protection by nets and wire-gauze screens where possible; continuous efforts for reduction of mosquitoes by major or minor works; and the establishment of a suitable organisation to carry out all the malaria preventive measures which shall be directed by a responsible chief officer who should present to the local government an annual report on malaria in the colony. The cost of these measures is estimated at £9000 per annum.

A number of appendices and addenda are placed at the end of the report, which is well worth the study of all who wish to acquaint themselves with the most modern methods of combating malaria.

Inborn Errors of Metabolism. By ARCHIBALD E. GARROD, D.M., M.A. Oxon. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 168. Price 3s. 6d. net.

THIS work is in substance the Croonian lectures delivered before the Royal College of Physicians of London in June, 1908, and published in THE LANCET shortly afterwards. They are now arranged in chapters with new matter added. It is said that "in any phenomenon of nature there is something of the marvellous;" this work shows that this is true and that it is manifest in the metabolic processes in living beings. Behind an apparently superficial uniformity exists a diversity no less real than that which is sometimes so obvious in structural anomalies, only this diversity being chemical and not morphological is much more difficult to examine. The inborn errors of metabolism specially dealt with are albinism, alkaptonuria, cystinuria, and pentosuria. The recent advances in chemical physiology have made possible the successful investigation of these obscure metabolic phenomena. We now know that each animal manufactures its own specific proteins and that special enzymes exist for special purposes. That great medium for the excretion of metabolic products—the urine—contains many substances which rank as abnormal constituents, which, however, are present in traces as by-products of metabolism; even such substances as cadaverin and hæmatoporphyrin have been discovered to be normally present in it. The author leaves aside that conspicuous group of maladies classed as "diseases of metabolism"—e.g., gout, obesity, and diabetes. Of those he deals with some are, and all of them probably are, present from birth, and, with one exception, bring in their train no serious morbid effects, do not call for treatment, and are little influenced by any therapeutic measure. One is tempted to regard them as four "metabolic sports"—the chemical analogues of structural malformations. That albinism is congenital and persists through life and is certainly harmless is well known. Alkaptonuria persists through life and is in the great majority inborn, though it may sometimes appear in disease; the evidence of cystinuria being congenital is more difficult to obtain; and as to pentosuria, discovered only in 1892, its inclusion is justified on other grounds, and evidence is accumulating of its harmlessness. Of all the four, Dr. Garrod's experience leads him to the belief that cystinuria is the least rare, and the only one of the four which can be classed as actually injurious, but even these effects are secondary. Another feature of this group is the liability for each of them to occur in several members of a family, most often in collaterals of the same generation born of normal parents; though in this respect they do not stand alone. There is some evidence of a special liability of the Jewish race to pentosuria.

Albinism has for its essential phenomenon the absence of pigments of the melanin group, but there is more than this, for it has been found that intravascular injections of nucleoproteins do not produce such intravascular clotting in the subjects of albinism as they cause in normally pigmented subjects. The Norway hare, when in its winter albino coat, behaves as an albino when injected with nucleo-protein.

The urine of an alkaptonuric—a very rare anomaly—seldom shows anything abnormal when freshly passed, but quickly darkens in contact with air, a phenomenon which is associated with the absorption of oxygen. Our knowledge of this anomaly only dates from 1858. Some alkaptonurics in later life develop a peculiar inky blackness of the cartilaginous structures—called by Virchow ochronosis—a condition that may also be produced by the prolonged absorption of carbolic acid. The excretion which is the essential feature of alkaptonuria is homogentisic acid with the empirical formula $C_8H_8O_4$, and the error of metabolism to which its presence is due is a failure to deal with the aromatic fractions of proteins, both of the food and tissues, in the ordinary way.

The chapter on cystinuria is both full and suggestive, and in it there is given an excellent account of the sulphur metabolism of the body. Like other inborn chemical errors, cystinuria occurs with greater frequency in males than in females. Its persistence and frequent transmission from generation to generation in a family are striking characteristics. The study of cystinuria leads the author to give an account of the chemistry of proteins and the amines, which are now known to play such an important part in the constitution of the protein molecule. Both cystinuria and alkaptonuria may be classed as an arrest rather than as a perversion of metabolism.

It was only in 1887 that arabinose was found to be a pentose—formerly it was placed in the hexose group—and not till 1892 was a pentose found in the urine, and most of the recorded cases have been met with in Germany. It is also a very rare anomaly and is not necessarily associated with any morbid symptoms, and there is a growing opinion that it is itself harmless and calls for no treatment. In a considerable number of cases there have been symptoms of neurasthenia.

The whole work is a thoughtful exposition of chemical problems of great complexity manifesting themselves in the sphere of the physician. To the elucidation of these problems the author brings all the knowledge of a thorough master of this branch of organic chemistry, as well as the observant and critical powers of a scientific physician.

Clinical Diagnosis: a Text-book of Clinical Microscopy and Clinical Chemistry for Medical Students, Laboratory Workers, and Practitioners of Medicine. By CHARLES PHILLIPS EMERSON, A.B., M.D., late Resident Physician, the Johns Hopkins Hospital. Second Edition. London and Philadelphia: J. B. Lippincott Company. Pp. 686. Price 21s. net.

DURING the past 20 years many excellent text-books have been written on "clinical diagnosis"—that is to say, on the clinical examination of the blood, the urine, and the gastric contents. There has naturally been a tendency for those observers working in the clinical laboratories to regard microscopical and chemical examinations apart from the actual patients from whom the various specimens were derived; in other words, only to deal with disease *in vitro*. To avoid the errors to which such a course is liable Dr. Emerson has made a point of considering work done in the laboratory from the clinical rather than from the purely laboratory point of view. That he has succeeded in writing a useful manual is proved by the fact that, although the work first appeared in 1906, a second edition has already been called for. In preparing this edition the efficiency of the volume as a practical work for medical practitioners and students has been raised in every possible way. Fully one-half the work has been re-written, resulting in a considerable increase in the number of pages. This enlargement has permitted the incorporation of much new matter throughout, including the bacteriology of the sputum and urine. This will add materially to the usefulness of the volume as a working handbook.

The first subject considered is the examination of the sputum, and here the microscopical characters of the morbid constituents are particularly well and minutely described. The various forms in which the epithelial cells of the alveoli may be met with are fully discussed, especial mention being made of the myelin globules and "drops," and of the "Herzfehlerzellen." The last-named is the term given to the cells filled with a golden yellow pigment; they only possess diagnostic importance when they occur in large numbers and over a long period of time. The granules are sometimes small, but often large. They have a translucent appearance, are not opaque; and certain cells seem to be diffusely stained. In chronic passive congestion, especially that due to mitral disease, these cells may give a gross colour to the sputum, the entire mass being of a rusty colour.

An excellent account is given of the clinical examination of the urine. The remarks on albuminuria are especially worthy of attention. The author discusses at length the occurrence of "albuminuria without definite renal lesion." With Spiegler's reagent it is hard to find an individual whose urine is really free from albumin. This being the case, there is no distinct line between physiological and pathological albuminuria except that of amount. Dr. Emerson defines "albuminuria" in these circumstances as "a condition in which serum albumin may be detected by the tests accepted in common use as standards, and the cases with small amounts of albumin which pass unnoticed by these tests and require special technique are not included." He quotes Hofmeister as saying that if Heller's test shows no ring in three minutes the urine is to be considered albumin-free. We endorse these remarks. The presence of minute quantities of albumin, recognisable only by reagents which are not employed in ordinary clinical work, corresponds to the presence of sugar in equally negligible amount as demonstrated by such a delicate test as safranin. Strange to say, this substance is not mentioned by Dr. Emerson as a test for glucose, although very accurate quantitative estimations may be made by its employment.

In discussing functional albuminuria, its occurrence amongst athletes is mentioned. Macfarland found this condition present in practically every football player whom he examined, but the albuminuria lasted for the most part only three or four hours. The same constituent is found in the urine of men taking part in other forms of athletics, bicycle riders and mountain climbers, those persons who exercise severely the leg and thigh muscles, especially to a degree beyond that to which they are accustomed; later, they are able to stand an equal amount of exercise without the albumin making its appearance. Dr. Emerson maintains that it is "only a question of limit; practically everyone can if he will produce albuminuria if he only over-exerts himself sufficiently." The occurrence of albuminuria following upon violent emotion or an unusually heavy proteid meal is also discussed, and the difficulties which may arise in assigning a physiological explanation are largely cleared away.

The chapter on the examination of the blood maintains the high standard shown in the rest of the work. The varieties of the white blood cells are described at length, and the characteristic blood changes found in the primary and secondary anæmias receive full attention. The technique necessary to obtain the opsonic index is given, but the full significance of the results from the point of view of diagnosis and as an aid to treatment is not explained according to the latest researches. Doubtless this defect will be remedied in a future edition.

The book contains a large number of excellent illustrations, the coloured plates being particularly good. We can cordially recommend the work to those of our readers who desire a trustworthy text-book on clinical diagnosis.

Common Disorders and Diseases of Childhood. By George Frederick Still, M.A., M.D. Cantab., F.R.C.P. Lond., Professor of Diseases of Children, King's College, London, &c. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 731. Price 15*s.* net.

In the preface to this volume the author modestly tells us that it has no claim to vie with the many text-books which deal with the whole subject of disease in childhood, and is not intended as a systematic work. Nevertheless, we are inclined to think that those who are interested in this subject will find it in many respects more valuable than an ordinary text-book. It is devoted to just those affections which are likely to be encountered in practice and treats of them in a practical way. The material is mainly drawn from Dr. Still's own large experience, and is therefore particularly valuable as being first-hand information, not a mere *réchauffé* of the statements of others, as text-books too often are. The subjects dealt with are too numerous to mention in detail. The first six chapters are devoted to the different aspects of infant feeding, and the seventh and eighth to the allied field of rickets and scurvy. A chapter on hypertrophy of the pylorus in infants might seem to be a little outside the scope of the work, as it can hardly be called a common condition; it is, however, of considerable importance. Digestive disorders of various kinds form the subject of Chapters IX. to XVII., followed by a discussion of the fever of obscure origin which is so often met with in children and which has in many cases a gastro-intestinal origin. The three next chapters deal with intestinal worms, with jaundice in children, and with the different affections called by different observers "croup." Diseases of the respiratory organs (bronchitis, broncho-pneumonia, pneumonia proper, and empyema) occupy the next four chapters, followed by three on the different forms of tuberculosis. Dr. Still believes that tuberculous infection is usually brought about by inhalation in children in whom the respiratory tract is specially vulnerable. To rheumatism and its allies, chorea and heart disease, four chapters are devoted, and two to nephritis and urinary disorders. The next 13 chapters are taken up with nervous disorders of all kinds, functional and organic, mental and bodily. On all of these Dr. Still's authority is well recognised. The concluding chapter is on congenital syphilis. Why it is placed here is not quite apparent, but it is none the less interesting for its postponement.

We cordially commend the book to all practitioners, and cannot praise it more highly than by saying that it is all that we should expect from its accomplished writer.

LIBRARY TABLE.

Diseases of the Digestive Canal (Œsophagus, Stomach, Intestines). By Dr. Paul Cohnheim, Specialist in Diseases of the Stomach and Intestines in Berlin. From the second German edition. Edited and translated by Dudley Fulton, M.D., Lecturer on Medicine, University of Southern California, Los Angeles. Illustrated. London and Philadelphia: J. B. Lippincott Company. 1909. Pp. 373. Price 16*s.* net.—Dr. Cohnheim's little book on diseases of the digestive system well deserved translation into English, being simply and practically written and showing signs of original investigation and personal experience. The translation is on the whole well done. The illustrations have been altered so as to show an earnest young American practitioner palpating a patient in place of the German physician of the original diagrams, and some new pictures have been added without, so far as we can see, adding much to the value of the work. We prefer the *format* of the German edition to that of the English one, as the former is lighter and thinner, with rather larger pages. The price of the translation is also, we believe, considerably higher than that of the original. Those, therefore, who are conversant with the German language will probably prefer the original, while those who are not so will be grateful for the translation.

The Birds of the British Islands. By Charles Stonham, C.M.G., F.R.C.S. Eng., F.Z.S. With illustrations by Lilian M. Medland. In 20 Parts. London: E. Grant Richards. 1909. Price 7*s.* 6*d.* each part.—Six parts of this interesting serial publication have appeared since our last review, and the standard of excellence both in text and illustration to which we have made previous reference is maintained. The author and the artist continue to work hand in hand to turn out a really authoritative text-book upon British birds. We are selecting for particular notice Volumes XIII. and XIV., the first of which contains the Columbæ and the Gallinæ, nearly all of which birds are so large that their pictures have to undergo a certain amount of compression to go neatly into the page. It is an undoubted drawback to these admirable pictorial representations that they have to be drawn occasionally out of scale, and now and again—as, for example, in the picture of the turtle-dove—we feel that the elegance of the page might well have been sacrificed to give us a life-size representation of the bird, which could, as a matter of fact, have been easily delineated on an available surface of nearly a foot square. The eye, at any rate at first, may fail to accommodate itself to the reduction which the artist has been compelled to suffer, and this will be recognised if we look at the representation of birds familiar in appearance to all of us, whether naturalists or not. The portraits of the pheasant, the partridge, and the grouse have all been reduced, and we have an instinctive feeling that the picture of the quail, which is drawn life-size, is more like its subject.

Mr. Stonham's notes are, as usual, replete with information, and the life-history of some of the birds described is very interesting. We wonder if it is common knowledge that the capercaillie of to-day is an alien bird introduced some 30 or 40 years ago from Sweden when the destruction of the pine forests had led to the extinction of the indigenous breed in the north of England and Scotland. The capercaillie, by the way, is an incontinent bird whose willingness to hybridise with the blackcock and the pheasant might well, we think, be taken advantage of in carrying out experiments in Mendelism, but possibly this has already occurred to practical workers. In the story of Pallas's sand-grouse no explanation is offered of the curious fact that the bird periodically invades us but cannot be proved to breed with us, while it is an interesting question for surmise whether the alteration in agricultural conditions in England will lead to the return among us of the birds which ceased to breed under the conditions prevalent in the palmy days of farming. Afforestation and the increase of pasture might, we suppose, lead to the recovery for our landscapes of many birds which are now no longer seen within our shores, or seen only as rare visitors, but the re-establishment, to take effect, will have to be in some numbers, for any stray sojourner is almost invariably shot by the first idiot who can hit it. Volume XIV. contains the orders Fulicariæ, under which we find crakes, rails, and coots, and in this volume there are mentioned two beautiful birds which, alas, are no longer to be counted with us—the crane and the great bustard. Cranes, we learn, were fairly common in England up to the sixteenth century, but there is no reference to them in Shakespeare, that learned field naturalist, and some of the allusions in literature are possibly due to confusion with herons. Cranes, we hear from Mr. Stonham, were protected by Act of Parliament at one time, and possibly the Act has never been repealed, but it is long since they have bred in this country. As a rare and occasional visitor the crane is asked to display great self-sacrifice, for the last record of its appearance, on May 23rd, 1908, has the additional note that the bird, a female, was shot and is now preserved in the Grosvenor Museum. A colony of great bustards, for so long the glory of Norfolk, was put down recently very near the spot where the last native pair were killed—namely, on the high heathland near Watton and Swaffham in Norfolk, by Lord Walsingham, whose efforts, however, to preserve the birds proved ineffective.

England is still the country of birds, and we should like to think that our superiority will be maintained, but it is a question whether we deserve it, for the general ignorance of birds and bird-life is great.

The Practice of Medicine. By the late M. CHARTERIS, M.D. Edin., Professor of Materia Medica and Therapeutics, Glasgow University, &c. Ninth edition. Edited by F. J. CHARTERIS, M.D. Glasg., Physician to Out-door Department, Western Infirmary, Glasgow, &c. London: J. and A. Churchill. 1909. Pp. 689. Price 9*s*. 6*d*. net.—A text-book which has attained its ninth edition should be fairly beyond the scope of criticism, and we need only say that, so far as we have been able to judge, the present edition is adequately brought up to date. The editor has been assisted by Dr. A. Grey Banks in the articles on the infectious fevers, but is alone responsible for the rest of the work, which has included much rewriting as well as revision. The book is practically a short text-book of medicine, suitable for students entering for the easier examinations. In many places its brevity makes it scarcely adequate for use without some supplemental reading. It is furnished with an appendix of therapeutical information, prescriptions, posological tables, incompatibles, &c.; also with a glossary of medical terms.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXVIII., No. 5. London: C. F. Clay, Cambridge University Press Warehouse. June 15th, 1909. Price 5*s*. 6*d*.—The contents of this number are: 1. On the Nature of the Fat Contained in the Liver, Kidney, and Heart, Part II., by Percival Hartley, Grocers' Company Research Scholar. Mr. Hartley demonstrated in a prior communication that the fats occurring in the liver, kidney, and heart yield on saponification a mixture of higher fatty acids which is far more complex than the mixture obtained by saponification of the connective-tissue fat. The fatty acids from the former sources have a very high iodine value, and when exposed to the air or when heated undergo changes whereby the iodine value diminishes, and at the same time a portion of the fatty acids is converted into a resinous substance which is insoluble in petroleum ether. In the present communication these fats are further investigated. In the fat of the liver linoleic acid and an acid having the formula $C_{20}H_{32}O_2$ are found. 2. A Mammalian Spinal Preparation, by C. S. Sherrington, University of Liverpool. In the production of this preparation the animal (cat) is deeply anæsthetised, the skin incised and reflected at the level of the axis after the insertion of a cannula into the trachea. A deep incision is made through the musculature behind the atlas, and a strong ligature is passed under the body of the atlas so as to compress the vertebral arteries. A second ligature surrounds the whole of the neck except the trachea, and decapitation is then performed. Hæmorrhage is slight. Artificial respiration is maintained. The skin flaps are brought together with the view of covering the exposed surface of the divided cord. The whole operation occupies about six minutes. The cord is found to be divided a little below the point of the calamus scriptorius. The preparation is well adapted for investigating muscular reflexes, which may be observed for ten hours. 3. A Stable Derivative of Hæmochromogen, by J. A. Milroy, M.A., M.D. Edin., from the Physiological Laboratory, Queen's University, Belfast. In this preparation nickel appears to replace iron. 4. The Carbon Monoxide Capacity of Reduced Acid Hæmatin, by J. A. Milroy, M.A., M.D. Edin., Belfast. 5. The Causes of Periodic or Cheyne-Stokes Breathing, by C. Gordon Douglas, B.M. Oxon., and J. S. Haldane, M.D. Edin., F.R.S., a note upon which paper occurs in another column. 6. The Regulation of Normal Breathing, by C. G. Douglas, B.M., and J. S. Haldane, M.D. Edin., F.R.S. This number also contains the Proceedings of the Physiological Society for March 27th, 1909.

Le Laryngoscope. Paris: Maloine. Price 75 centimes. —The July number contains an original article by Dr. Texier and Dr. Molinié of Nantes on Foreign Bodies in the Larynges of Children, with a great many illustrative cases. This article, which is very interesting and complete, is followed by one on Aneurysms of the Ascending Aorta and the Transverse Aorta, with the complete Mediastinal Syndrome of Symptoms, by Professor Boinet, and an interesting little paper on the Treatment of Certain Rebellious Nasal Synechiæ, by Dr. Jacques and Dr. Mathieu. It is a very well got up little journal, and this number fully justifies the favourable impression which we formed of its predecessors.

Verhandlungen des Vereins Deutschen Laryngologen. (*Proceedings of the German Laryngological Society.*) Würzburg: Stube. 1908. Price 2 marks 50 pfening.—At this meeting nine papers were read, the subjects and authors being as follows: Carcinoma of the Hypopharynx, by Dr. Körner; the Employment of Fulguration in Laryngology, by Dr. von Eichhorn; Diseases of the Sphenoidal Sinus in association with Scarlet Fever, by Dr. Killian; a paper on Experiences in Regard to Complications of Disease of the Sphenoidal Sinus, and a paper on the Flow of Saliva through the Nose, by Dr. von Eichen; a paper on Light Therapy in Acute Sphenoidal Sinus Disease, and a paper on a Contribution to Submucous Resection, by Dr. Brünings; a case of Primary Tuberculosis of the Palate, by Dr. Goris; and a case of Primary Syphilitic Infection of the Septum Nasi, by Dr. Neugas.

New Inventions.

INSTRUMENTS FOR GASTRO-ENTEROSTOMY AND CHOLECYSTOSTOMY.

DURING the performance of gastro-enterostomy or intestinal anastomosis it frequently happens that the pouting mucous membrane of the already sutured half of the bowel is apt to be in the way of the needle while the anterior or return half of the mucous membrane is being sutured. To aid in the application of this suture I have had a protector made with ends of different sizes for gastric or intestinal work (Fig. 1). It is applied after the posterior suture line is complete and serves to depress the ridge of mucous membrane, at the same time affording a smooth surface over which the point of the needle readily glides. It is easily withdrawn before the suture is completed. A three-bladed coaptation forceps (Fig. 2) (originally designed for the coaptation of skin edges) has also proved useful for lifting up in apposition the edges to be sewn. The gall-stone bowl (Fig. 3) is of assistance in the cleanly performance of cholecystostomy. The apex of the gall-bladder, after having been drawn through a hole in the centre of a sheet of thin rubber, is seized with two pairs of Porrier's forceps which are allowed to hang over the projections on either side of the lip of the bowl, the gall-bladder is opened between them, and its contents readily scooped into the bowl which rests upon the lower part of the abdominal incision. The above instruments have been made for me by Messrs. Down Bros.

HAROLD UPCOTT, F.R.C.S. Eng.,
Hull. Honorary Assistant Surgeon, Hull Royal Infirmary.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the office, 37, Soho-square, W., on June 25th, under the presidency of Sir HENRY MORRIS, Bart., the treasurer of the College. He was supported by Sir R. Douglas Powell, Bart., Sir Constantine Holman, Mr. J. Paul Bush, C.M.G., Dr. Charles Caldecott, Dr. Charles W. Chapman, Dr. William Collier, Dr. Clement Godson, Dr. F. de Havilland Hall, Mr. H. E. H. Matthews, Mr. John H. Morgan, C.V.O., Rev. E. W. Northey, Dr. Guthrie Rankin, Mr. Clement Locke Smiles, Dr. Frederick Taylor, Mr. W. Bramley Taylor, Dr. J. Roberts Thomson, and Dr. W. Essex Wynter.

The proceedings commenced with the passing of a resolution expressing the cordial congratulations of the meeting on the well-deserved honour of a baronetcy conferred upon Sir Henry Morris by His Majesty the King. This was moved by Sir CONSTANTINE HOLMAN, the late treasurer of the College, seconded by Sir R. DOUGLAS POWELL, and carried by acclamation.

The SECRETARY having read the result of the voting for pensionerships and foundation scholarships, which have already been published in the columns of THE LANCET, the resolution as to the adoption of the report for the past year was moved by the Chairman, who referred to the salient points contained therein, and was carried unanimously. The report stated that although the receipts from subscriptions and donations were slightly lower than in the previous year there was a surplus on the ordinary income and expenditure account of £432 14s. 7d. A sum of £5498 11s. 9d. was spent on extending the buildings at Epsom in 1908, of which amount £883 was the balance of the cost of the new lavatory block, and £4614 the expenditure (on account) of the new Markham Skerritt laboratories. In the report for the year 1897 the governors were informed that under the will of the late Dr. Henry Fearnside, of Bournemouth, the residue of his estate would pass to the College for the Endowment Fund after the decease of his widow. Owing to Mrs. Fearnside's death in 1908 the residue would shortly be handed over to the Endowment Fund. The council hoped that friends of the institution would do their best to secure fresh annual subscribers, since death removes annually many who had been staunch supporters of the College from soon after its foundation. If members of the profession who are unable to contribute large amounts would subscribe a guinea, or even half-a-guinea, annually; and if all medical men would plead the cause of the foundation to their well-to-do relatives and friends the present number of 50 pensioners and 50 foundation scholars could be maintained without difficulty. As the total assured income of the College, including the dividends from the Fearnside legacy fund but deducting interest on mortgages, is under £2500 a year, whilst the maintenance of the 50 pensionerships and 50 foundation scholarships requires close upon £7000 annually, a sum of £4500 a year must be obtained from voluntary contributions. In an appeal recently issued by the honorary treasurer attention was drawn to the fact that whilst the names of 39,827 persons are contained in the Medical Register, under 2200 medical practitioners—that is to say, only one-eighteenth of the profession—are annual subscribers to the foundation. Under the will of the late Miss Annie Graham Sewell, one-fifth of the residue of her estate has been left to the College for the purpose of creating pensionerships under the following conditions: "Pensions shall be provided of not less than £20, nor more than £50, each; such pensions shall be called or known as the 'Brodie Sewell Pensions,' and shall be allocated or granted to the objects of the institution or charity, but in selecting pensioners for 'Brodie Sewell Pensions' preference shall always be given to the widows and spinster daughters of medical practitioners." In accordance with the will of the testatrix, the first presentations to these pensionerships will be made by her executors.

The report further pointed out that the new building to provide further class-rooms, better accommodation for teaching science, and a room for the use of the day boys, was opened in March last. The laboratories, which are to be called permanently the "Markham Skerritt Laboratories," have been well equipped, and will afford efficient means of instruction in physics and biology to all boys who require these subjects. After giving careful consideration to a scheme for the provision of further buildings which are urgently needed in view of the rapid growth of the school, the council decided to erect a new gymnasium, new music rooms, and a new workshop, and to provide a central heating plant having sufficient power to heat all the new buildings, together with Granville House, the large school, and the chemical laboratory. These extensions and improvements will probably cost over £6000, but though this sum is large the council feels assured that a consistent and definite scheme of extension is the most economical course that can be followed. That the school is growing in importance and popularity may be seen from the fact that there are 282 boys at present in the College, whereas in the same term five years ago there were only 235 boys. Old Epsomians have raised a subscription for the purpose of erecting a stained-glass window in the College chapel as a memorial to the late Archdeacon Thornton, who was the first headmaster of the College.

The report concluded with the honours of the year, which are as follows:—H. A. Baylis has won an open classical exhibition at Jesus College, Oxford; J. M. L. Bogle an open studentship at the University of Liverpool; G. K. Bowes a junior studentship for science at Christ Church, Oxford; and C. A. Mallam a classical exhibition at Keble College, Oxford. Ten boys have passed the whole or a part of the preliminary scientific examination for the degree of M.B., B.S. of the University of London, 18 have passed the matriculation examination of the same University, 11 have gained the higher certificate of the Oxford and Cambridge Schools Examination Board, and 18 have gained the lower certificate.

The retiring members of the council and the auditors were then reappointed; Dr. de Havilland Hall was elected a vice-president of the College; and various alterations and additions were made to the by-laws of the College.

The meeting closed with a vote of thanks to the chairman.

THE LANCET.

LONDON: SATURDAY, JULY 3, 1909.

Public Health and Social Conditions.

THE President of the Local Government Board has recently issued in a Blue-book[1] of more than one hundred folio pages a collection of statistical memoranda relating to public health and social conditions, presumably for the instruction of the large body of local officers who depend on the Board for authority and guidance in the discharge of their various duties. The graphic representation of statistics is, we believe, a favourite device with Mr. JOHN BURNS, who believes, like ourselves, that such appeals to the eye are particularly arresting and convincing, and we are glad that he has thought proper to summarise in one volume practically all available statistics relating to the work of his important office, and to illustrate them as completely as possible by charts and diagrams, which, although by no means new, are inserted on the authority of the several State departments concerned. The issue of a statistical summary on the present lines constitutes an entirely new departure on the part of the central authority, and we shall be interested to learn how far its authoritative publication is appreciated by the public officials for whose edification it has apparently been designed. The compilation has been entrusted to Mr. C. F. A. HORE of the Local Government Board, and the sections relating to the public health and to pauperism have been produced under the direction of Dr. A. NEWSHOLME and Mr. J. S. DAVY respectively. From an introductory note we learn that the volume is designed to illustrate in a convenient and readily intelligible form the following conditions: (1) the growth of population and the changes in the occupations of the people; (2) the principal facts respecting public health and mortality, together with an account of sanitary administration, central as well as local; (3) the material features of industrial conditions—e.g., the changes of occupation, the rise of wages and the decline in prices of the necessaries of life, the fluctuations in the labour market, and the results of measures for dealing with unemployment; and (4) the subject of Poor-law relief, the decline of pauperism, and its cost in the present as compared with the past. Other sections in the volume deal with the subjects of taxation and the growth of local expenditure for sanitary and other purposes. While each topic is dealt with as succinctly as possible, the endeavour has been made to provide materials for a historical survey of the subject, many of the tables and charts having been carried back over a period of more than a half century. The compilers confess that their work contains little that can claim the merit of originality. Much of the material is derived from reports issued from time to time by Government departments, although not previously available in connected form. To effect such connexion, whilst at the same time restricting the work within reasonable limits, a few only of the most important topics, and those chiefly relating to administrative matters especially bearing upon the work of the recent Poor-law Commission, have been selected for comment.

In the present article our observations will relate almost exclusively to the first two of the sections into which, as we have said, the work is divided, inasmuch as they contain data which are of chief interest to our medical readers. In the first section the principal facts are summarised concerning the growth and distribution of the population of these islands. The actual figures, having been already published in the census reports of the Registrar-General, are omitted here. But it is worthy of remark, as showing the rapid growth of the British population, that within the half-century ended in 1901 the number of persons living showed an increase of more than 50 per cent. It has frequently been stated that the period of maximum increase of the population corresponds to the period of maximum birth-rate, which was in 1871–81. This decade includes the years 1871–75, when, as shown by the decline of unemployment and pauperism, and by the rise in the average rate of wages, the country enjoyed a marked increase of prosperity. In the intercensal period 1881–91 there was a fall in the relative increase of the population, but the more recent decade again shows a recovery. The factors which determine the growth of population are (*a*) the balance between emigration and immigration, and (*b*) the difference between the births and the deaths. It is impossible to determine the extent to which the community gains by immigration, because the returns include foreigners only temporarily resident in this country, while the offspring of aliens born since their arrival here are excluded. It should be noted, however, that ever since the establishment of civil registration the number of births has invariably exceeded the number of deaths, and that the ratio of births to population has for the last three decades been declining. The ratio of deaths has also shown a decrease, although this decrease does not quite balance the fall in the birth-rate. The net result is that the average natural increase of the population—i.e., the balance between natality and mortality—has slightly declined within the last 30 years. In the second section of the work the general subject of public health is dealt with by Dr. NEWSHOLME, who ably discusses, in the first place, the evidence as to the health of the community afforded by the recorded mortality, especially that of infants, the death-rates from the principal diseases, and the mortality in the various industries. Secondly, he considers the development of public health administration, particularly in regard to the measures for general sanitation, for the improvement of unhealthy and overcrowded areas, and for rehousing the displaced inhabitants; and finally, the condition of the public medical service under central and local control. It is matter of common knowledge that recently the general health of the people of this country has very considerably improved; indeed, it would be surprising if it were otherwise, having regard to the enormous sums annually expended in safeguarding the public health. A similar, but hardly equal, improvement has taken place in the health of most other European nations. The Registrar-General has for some years past published returns of mortality for the principal colonial and foreign States, setting forth not only the crude death-rate from all causes in terms of the estimated population at all ages, but, what is more important from a sanitary standpoint, the loss of life due to the more prevalent diseases. Although these returns are interesting and valuable as records of fact, they nevertheless lack that precision which should attach to such records wherever they are regarded as criteria of the degree of health or of longevity of communities placed in comparison. Unfortunately, the colonial and foreign returns published by the Registrar-General of England are not corrected for differences of age and sex constitution of the several populations, and therefore, strictly speaking, they are to that extent untrustworthy. In England and Wales, however, careful correction for this disturbing factor has for many years been made at Somerset House, so that the mortality of the principal cities and other urban areas becomes fairly comparable with that of the rural districts. The latest Blue-book tells us that after correction of this kind there is an average difference of 23 per cent. in the mortality of the urban and rural areas. The greater mortality in urban areas is attributable, among many causes, to the more serious risk of life incidental to certain industrial occupations, to the greater liability to infection and other risks attending the undue aggregation of population, and to the general lowering of health attaching to the insanitary surroundings of populous places. We know that such conditions are remediable by well-directed public action, and it is only just to acknowledge that the recent satisfactory decline in British mortality, especially in that of the more prevalent diseases, is in a large measure due to the sanitary progress of recent years.

---

[1] Statistical Memoranda and Charts prepared in the Local Government Board relating to Public Health and Social Conditions. Eyre and Spottiswoode, Limited. 5s. 1909.

The elaborate statistics that accompany this volume furnish striking evidence of the improved condition of public health in this country. The average duration of life has been prolonged, the death-rate has fallen to an unprecedentedly low figure, and diseases such as pulmonary tuberculosis, enteric fever, and small-pox have become far less prevalent. Having regard to his position as medical adviser of the Board, we are prepared to find that Dr. Newsholme has devoted a large portion of his memorandum to a review of public health administration in England and Wales. The story of that administration is one of steady progress. As a result of the great outbreak of cholera which visited this country in 1831 a Royal Commission was appointed, shortly after which year—viz., in 1847—the Towns Improvement Clauses Act was passed, and in the following year the first Public Health Act. Under that enactment a general Board of Health was established, with power to sanction the constitution of local boards of health on petition of the inhabitants concerned. But it was not until 1871 that the organisation of public health authorities was recast and placed on a fairly satisfactory footing. Under the Act of that year the Local Government Board was made the Central Public Health Authority, and was invested with the powers previously possessed by the Privy Council and the Home Office in relation to sanitary authorities. The whole of England and Wales was under that Act divided into urban and rural sanitary districts, but the powers scattered through several Acts were not consolidated into an effective measure until 1875, in which year the Magna Charta of public health obtained a place on the Statute Book, and this still remains the chief instrument for the promotion of public health in all parts of England outside the metropolis. The publication of this latest Blue-book shows in a graphic manner our present position with regard to public health, and proves that Mr. Burns and his medical adviser are alert to ensure that the steady rate of progress shall be maintained.

A Standard Diet.

From time to time our most cherished beliefs receive rude shocks as the advance of knowledge brings to light new and unexpected truths, and it may happen that views which seemed most firmly rooted are exhibited in the guise of mere fragile hypotheses. Not many years ago the average dietetic needs of mankind seemed to have been securely ascertained for all time by the researches of Voit and others, which formed the basis of definite dogmatic assertions set out in all text-books of physiology. In recent years, however, doubt has been thrown on the correctness of these observations, chiefly by the researches of Chittenden, on the scientific side, and among the popular world similar doubts have been raised as to the wisdom of ordinary methods of feeding by the energetic preaching of that enthusiast, Mr. Horace Fletcher, who holds that most of the ills of life may be avoided by prolonged mastication of our food. According to this theory of life a little food is made not only to last a long time but also to go a long way, a very small quantity of fuel being apparently needed by a machine which is stoked in this peculiar manner. Since modern society is not unlike that of ancient Athens in its desire for some new thing, and as health and hygiene are fields in which the follies of persons with a tendency to mental obliquity may be actually dangerous, it is well that the credentials of the new doctrines should be carefully scrutinised. This task has been recently undertaken by Sir James Crichton-Browne, whose presidential address to the Section of Preventive Medicine at the meeting of the Royal Institute of Public Health in 1908 has now been issued in book form[1] and thus rendered attainable by the world at large. In the course of it he brings forward a large amount of information as to the practical experience which has been gained in different parts of the world and in different circumstances with regard to the minimum quantity of food needed by the human animal for the proper maintenance of its strength and activity. The data furnished are far from supporting the new doctrines, and are indeed very difficult to reconcile therewith.

Exact measurements of dietetic requirements are most easily made in the field of protein metabolism, and it is to this that Sir James Crichton-Browne's inquiry is mainly directed. The standard laid down by Voit demanded 118 grammes of protein food for an average man doing ordinary work, *and more recently* ATWATER *slightly raised this* amount, calculating the proper protein ration as 125 grammes. CHITTENDEN, on the other hand, holds as the result of his observations that 60 grammes is adequate for a man of average weight. The ordinary diet of the Japanese is quoted in support of this calculation, as OSHIMA puts their daily intake of protein at just this figure; but Sir JAMES CRICHTON-BROWNE rightly points out that the argument is inconclusive, since the Japanese are a small race and therefore need a quantity of food proportionately less than the European. He even suggests that this smallness of stature may be due to defective supply of food. It is usual to credit the European races with more energy and endurance than the Asiatic, and these qualities are sometimes attributed to the greater protein intake of the former. The vigour and endurance displayed by the Japanese have, however, tended to throw doubt both on the fact and on its explanation, so that a proper understanding of the dietetic habits of this remarkable people is most desirable. It is interesting to note that in the Japanese army during the recent campaign in Manchuria the protein ration supplied was more abundant than had fallen to the lot of any army in the field in previous times. Returning to European experiences, we find that attempts have from time to time been made to cut down the diet of prisoners in gaol to the lowest limit compatible with existence, and thus experiments have been made which afford interesting light on the problem of diet. Some time ago in England ordinary prisoners were kept on a diet containing only 57 grammes of protein, and credible testimony shows that this resulted in a state of semi-starvation; while for convicts on what is termed light labour even 130 grammes proved insufficient. In France a ration containing 94 grammes of protein was found by GAUTIER to be too poor in meat. These observations actually made on a considerable number of subjects are very difficult to reconcile with the views of CHITTENDEN as to the proper protein ration. It must, of course, always be borne in mind that in dealing with proteins we are dealing only with a portion of the whole field of diet, and that probably a larger allowance of carbohydrates and fats may for a time compensate for slight defects of protein constituents in the food. Nevertheless, a certain amount of proteins must be supplied in some form or other, and there is an irreducible minimum below which continuous loss of substance must occur. As to the proper average amount experience tends to support the ordinary dietetic usages of mankind.

---

[1] *Parcimony in Nutrition.* By Sir James Crichton-Browne, M.D., LL.D., F.R.S., Lord Chancellor's Visitor in Lunacy, London. London and New York; Funk and Wagnalls Co. 1909. Pp. 111. Price 3s.

It is sometimes said that in such a matter as diet rules are unnecessary and that we may safely be guided by appetite alone, the truest indicator of the need for food. A little reflection will raise doubts as to the feasibility of relying on this measure of what is requisite. To the consciousness of the individual it is difficult or impossible to distinguish between the desire for food arising from true hunger and that produced by the sight of food which is attractive to the palate; in other words, to distinguish between need and greed. To the ascetic living on the plainest fare this problem might not present the same difficulty, but it is unlikely that asceticism will largely replace the luxurious habits of modern civilisation. Even on monastic fare difficulties might arise, *for appetite is stayed by mere bulk of material ingested*, at least for a time. Thus a meal of rice is temporarily most satisfying, but as digestion proceeds the lack of sustenance contained in the food in proportion to its bulk becomes, to the European at all events, unpleasantly obvious. If, then, individual consciousness is a fallible guide, it is difficult to place much reliance on popular habits as a criterion of what is necessary. When, however, the habits coincide fairly closely with the results of experiment they may be provisionally accepted, and popular usage certainly demands a protein ration far above CHITTENDEN'S figures. On the whole, we do not think it would be wise for healthy individuals to make any sudden alteration in their habits of life in the direction of adopting a strict Chittenden diet. There is some evidence, derived from experiments on animals, to show that such a proceeding leads to a diminution in the resistance of the body to infective diseases. Nevertheless, it is undoubted that the well-to-do classes at all events—and we may include in this class not only the nominally rich but all those who have the means to live without oppressive forethought for the morrow—have a tendency to indulge excessively in food, especially in that of an animal nature. Good may therefore ensue if the views recently propounded result in some curtailment of the consumption of meat, which has increased so markedly in recent years. To those who have reached or passed middle life such self-restraint is specially advisable, above all if they are compelled to lead somewhat sedentary lives. To such, a reduction of the protein ration of youth, and moderation *in consumption even* of the other forms of food, may be safely commended. As the fire of life burns less fiercely and the output of energy is smaller, so the fuel supplied should be reduced, that the system may not be clogged with ashes and half-burnt cinders whereby the activity of the whole machine is from time to time impaired and may even be prematurely arrested.

Enteric Fever due to Shell-fish.

THE problem of tracking an outbreak of infective disease to its origin often presents difficulties of no mean magnitude and necessitates in the tracker qualities which are popularly associated rather with criminal investigations than with medical and sanitary studies. We are inclined to attribute the faculties of accurate observation and close deductive reasoning necessary for such inquiries to Mr. SHERLOCK HOLMES rather than to his medical friend, Dr. WATSON. This is wrong, and we have often felt that the novelist did an injustice to the medical profession, his own profession, moreover, when he used a member of it as a foil to his hero, for our sanitarians need have no fear of challenging comparison with legal or criminal investigators. A conspicuous example of such reasoning applied to the problems of public health is afforded in the noteworthy paper recently read by Dr. L. W. DARRA MAIR before the Epidemiological Section of the Royal Society of Medicine on the subject of the prevalence of enteric fever in Belfast and of its mode of causation. For many years this city held an *undesirable* pre-eminence in respect to its death-rate from enteric fever, the rate of mortality per 1000 persons living being in the decade 1891–1900 0·86, as compared with an average of about 0·32 among 19 other large towns, while in the following decennium the Belfast figure was 0·57, as against 0·19 in the other towns. The need for special inquiry into the cause of such prevalence was therefore clear. The two methods of the spread of enteric fever which are most widely recognised are by means of water and by defective disposal of sewage. These were therefore first investigated by Dr. Mair and found insufficient to account for the phenomena of spread in Belfast. It was obvious that the distribution of the cases did not correspond at all accurately with the areas supplied from any one of the water intakes, and the onset of the outbreaks had not that sudden "explosive" character which is associated with those due to contaminated water. On the other hand, there were factors which were quite consonant with the possible influence of defective sanitary arrangements on the prevalence of the disease, as a considerable section of the city was in the earlier part of the period of time covered by the investigation badly furnished with sewers and largely dependent on a system of privy-middens. Nevertheless, this hypothesis had also to be discarded, as it was found that improvement in sewerage had not been followed by any decline in the prevalence of the fever; indeed, there had actually been an increase in the latter corresponding with the provision of a scheme of drainage by which the sewage of the town was carried out into Belfast Lough. Apart from this peculiar phenomenon the only outstanding fact bearing on the problem was that the areas of maximum infection corresponded pretty accurately with those parts of the city which were mainly inhabited by the labouring classes.

These two hypotheses being thus rejected, there remained that of the spread of enteric fever by means of infected shell-fish. This mode of causation has often been traced in isolated outbreaks, but, so far as we are aware, it has not hitherto been found answerable for continued epidemic prevalence of enteric fever in particular localities. Nevertheless, in the present instance this mode of explanation was found to correspond closely with the observed features of the disease. There was in the first place plenty of opportunity for such infection, as cockles taken from the shore of the Lough were largely consumed in the town, being not only hawked about the streets by local vendors, but also collected by many of the inhabitants themselves, and eaten for the most part raw. A decline in the incidence of enteric fever occurred in the early "eighties" coincidently with the reclamation of a large portion of the foreshore from which the shell-fish were taken, while the introduction of the new scheme of sewerage seemed actually to inaugurate a rise in the number of attacks, doubtless owing to the carriage to the sea of a larger portion of the whole sewage of the town, and the consequent greater infection of the cockles lying on the shore. Special facilities for this pollution of the shore waters were traceable, not only to the sluggishness of the tides at this point which thus failed to carry off the offending material, but also to a breakdown of the actual sewer, which leaked over a considerable portion of the foreshore. The conditions thus resulted in a discharge of crude sewage, amounting to 12 or 15 millions of gallons daily, into "shallow and sluggish water in the immediate vicinity of shell-fish beds daily drawn upon for public consumption." Several minor features tended to confirm this view of the causation of the epidemic. Thus it was noted that the Jewish population—not a large one indeed in this locality—was singularly free from the scourge, and this fact was readily explicable in view of their abstinence from shell-fish as an article of food; whereas in outbreaks elsewhere, in which the disease had been associated with the distribution of infected milk, they had not shown any racial immunity. Further, the inhabitants of public institutions, such as the hospitals, the workhouse, and the prison, who would naturally have no opportunities of obtaining shell-fish for consumption, were on the whole free from enteric fever. Finally, certain peculiarities in the seasonal incidence of the disease in Belfast admitted of explanation on this hypothesis. It was found that the smallest number of cases occurred here in the winter months, December to February, while the incidence rose in the spring and was highest in August and September, whereas in London and in Manchester, which are compared in Dr. Mair's paper, the spring months show no such rise, being, indeed, specially free from enteric fever, while the morbidity is in September and in October. Now it is true that in Belfast there are no special seasons for the consumption of shell-fish, but the indulgence in certain of these delicacies is confessedly greatest in the spring and summer, since the pleasant weather tempts many persons to frequent the shore and gather the cockles.

There can be little doubt that in any epidemic of enteric fever other causes take part in spreading the epidemic besides the original source of infection. Thus, as Dr. A. Newsholme pointed out in the discussion which followed Dr. Mair's paper, the existence of privy-middens may readily lead to extension of an epidemic which is once established, while the presence of a certain proportion of "typhoid-carriers" among those classes of the population who are engaged in the preparation of food constitutes another source of danger. Nevertheless, it was generally admitted by the section of the Royal Society of Medicine, and we think on excellent grounds, that Dr. Mair had thoroughly established his position with regard to the Belfast epidemic. The whole paper constituted a most valuable contribution to the study of this source of enteric fever, and will doubtless lead to stricter control being exercised by public health authorities all over the country with regard to the conditions which prevail as to the collection, storage, and sale of such dangerous articles of diet as cockles and mussels.

The Congress on Alcoholism.—The International Congress on Alcoholism will meet in London at the Imperial Institute on July 19th and following days. The Duke of Connaught will preside, and the list of vice-presidents contains many influential names. Various Governments in both hemispheres have appointed official representatives, those for France being M. Riémain and M. G. Barbey, while those of the United States of America include, among others, Surgeon F. L. Pleadwell of the U.S. Navy, and Dr. T. D. Crothers of Hartford, Connecticut.

Annotations.

"Ne quid nimis."

DARWIN, EVOLUTION, AND PATHOLOGY.

THE recent celebrations at Cambridge of the centenary of the birth of Charles Darwin and of the fiftieth anniversary of the publication of the "Origin of Species" were remarkable not only for the wide area from which those taking part in the celebration were drawn, but also, and even more, for the unanimity with which the importance of Darwin's teaching was appreciated. The meeting at Cambridge emphasised the fact that the few who seem to claim that Darwinism has been superseded are either themselves misunderstood or are not fully acquainted with what Darwin really taught. Those who know his teaching best are best able to appreciate how widely his ideas have penetrated into every science and how adaptable in many directions those ideas were and are, so that it is extremely difficult to say of any work done since his era that it is directly antagonistic to his theories. The central and general idea of evolution is very old, but until Darwin arose, no simple or reasonable explanation had been given of the method by which this evolution might be brought about. Many had recognised the apparently progressive change in organic forms, so that there was an almost continuous slope from the lowest forms to the highest, but it was hardly definitely recognised that all these organisms might be parts of a true genealogical tree. Darwin was perfectly original in pointing out that while change in organic forms depended on the variations and peculiarities present in every organism, the persistence of these changes was dependent upon their power of agreement with the conditions in which the organisms were placed. The question whether the variations are great and immediate or slow and little is on another plane; the main doctrine depends on the survival of those forms which are best adapted to the circumstances in which they find themselves. The evolution of plants and animals is now universally admitted, but it is not sufficiently perceived that the doctrine of evolution is applicable to many other sciences than biology. Recent researches have indicated that in matter itself there has been an evolution of elements with the ultimate survival of those which could endure the conditions of their environment. It is, however, in the realm of pathology that the importance of evolution is of the greatest interest to us. In the never-ending struggle between an animal and the parasitic micro-organisms invading it, forms are slowly evolved which have greater and greater power of resistance to the microbic attacks, and thus in time a racial immunity of greater or less power is reached. This is well exhibited, for example, in the case of measles. Through centuries measles has existed as an endemic disease in this country, and by a selective removal of those in whom the disease was of special severity a race has arisen in whom measles is comparatively mild, though even at present some 13,000 die yearly from the disease in England and Wales. That this diminution of the severity of measles is in no way the result of a weakening of the virus is conclusively shown by the result of the introduction of the disease to a race to which the disease is new, when an appalling mortality rate will occur, as was terribly exemplified in the Fiji Islands some 35 years ago. During the proceedings in honour of Darwin at Cambridge Professor Metchnikoff referred to the evolution of resistant strains of bacteria. In the lower organisms which possess to a high degree the power of rapid multiplication we are able to see for ourselves the evolutionary process at work. To the bacterium which passes through hundreds of generations in a day, that day is as a thousand years to higher organisms, and a bacterium may undergo changes in a few hours by which its qualities are absolutely modified. Its virulence as an agent of disease may be enormously increased or profoundly diminished. The attenuation of a virus, while passing through the body of a resistant host, is probably only another example of rapid evolutionary changes in micro-organisms. Such widely differing topics as racial addiction to alcohol and structural modification in parasites can be discussed from their Darwinian side, but we have said enough to show that by a correct appreciation of evolution and the doctrine of the survival of the fittest the medical man is enabled to penetrate more deeply into the mechanism of morbid processes, and to understand more fully the complexities of immunity which prevail in the animal world.

THE BIRTHDAY HONOURS.

THE list of Birthday Honours is somewhat long and we might add is only redeemed from mediocrity by the honours accorded to the medical and scientific professions. No new peers are created, but among those who have received a baronetcy of the United Kingdom is Mr. Henry Morris, the President of the Royal College of Surgeons and the treasurer of the Imperial Cancer Research Fund. Sir Henry Morris, of course, is well known to all medical men for his excellent work in surgery, especially that connected with the kidneys and the other urinary organs, as well as for his munificent gifts to the Middlesex Hospital for the endowment fund of the medical school and his energetic work in support of Epsom College. The other member of the medical profession to receive a baronetcy is Sir Dyce Duckworth, who is well known as a consulting physician to St. Bartholomew's Hospital, who has been medical referee to the Treasury since 1894 and treasurer of the Royal College of Physicians of London since 1884. Among those to receive the honour of knighthood is Mr. Francis Galton, F.R.S., a grandson of Dr. Erasmus Darwin, a man eminent in many branches of science, and the author of that delightful little work, "The Art of Travel." The Royal Army Medical Corps receives an honour in the shape of a knighthood granted to Lieutenant-Colonel W. B. Leishman, M.B., R.A.M.C., so well known for his researches in bacteriology and protozoology. Mr. Thomas Edward Thorpe, C.B., F.R.S., who also receives a knighthood, is the eminent chemist who is the chief of the Government Laboratory. In the Order of the Bath the Right Hon. Sir Ernest Cassel, so well known for his munificent gift of £200,000 for charity which was applied by His Majesty the King for the provision of sanatoriums for tuberculous patients, receives a G.C.B. Surgeon-General Lionel Dixon Spencer, M.D., I.M.S., and honorary surgeon to His Majesty, is made a Knight Commander of the Bath, and among those to receive a Companionship of the Order are Surgeon-General Hayward Reader Whitehead, F.R.C.S., R.A.M.C., principal medical officer, Southern Command, and Colonel de Burgh Birch, M.D. Lieutenant-Colonel Robert Neil Campbell, M.B., I.M.S., officiating Inspector-General of Civil Hospitals in Eastern Bengal and Assam, and Mr. Edgar Thurston, L.R.C.P., the Superintendent of the Government Central Museum of the Province of Madras, are made Companions of the Order of the Indian Empire, while the Kaisar-i-Hind gold medal has been awarded to Dr. Temulji Bhikaji Nariman, L.M., F.R.M.S., of Bombay. Professor William John Ritchie Simpson, M.D., well known for his services in the matter of plague, receives a Companionship of the Order of St. Michael and St. George. Among other names we may mention that of Mr. F. J. Campbell, LL.D., who, blind himself, has done such good work in the establishment and guidance of the Royal Normal College for the Blind and who has been honoured with a knighthood, and the Rev. Hermann Adler, Ph.D., the Chief Rabbi, who has been made a Commander of the Victorian Order. The theatrical profession, which is always ready to spend itself in the cause of charity, and especially in that of hospitals, is honoured in two of its members who receive knighthoods, Mr. A. W. Pinero and Mr. Herbert Beerbohm Tree.

THE PROTEIN CONTENT OF THE CEREBRO-SPINAL FLUID IN GENERAL PARALYSIS.

That protein is a normal constituent of the cerebro-spinal fluid has been known for some 40 years. While an increase in the protein amount in cases of inflammation of the meninges has been commonly recognised, it is only within the last few years that a similar and constant increase in parasyphilitic conditions has been described. Pathological increase in the total protein (albumins and globulins) is now regarded as a definite feature of the cerebro-spinal fluid in general paralysis, an increase generally, though not necessarily, parallel in extent to the degree of lymphocytosis. Further, the lymphocytosis due to parasyphilis is more constantly accompanied by an increase in the protein content than is the lymphocytosis due to tertiary syphilis of the nervous system. The protein increase may amount to four times the normal quantity, and it is easily recognised by any of the simple qualitative tests. The study of the form of protein present is of greater interest and importance. In the normal fluid globulin, probably serum globulin, is the form commonly met with; if albumin is present it must be in exceedingly small amount. In the fluid of the general paralytic, as is pointed out by Dr. Ernest Jones in the current number of the *Review of Neurology and Psychiatry*, the chemical changes are not yet determined with accuracy, and therefore the question is rather to decide which chemical reactions are the most characteristic. The reaction which has been recently introduced by Noguchi deserves mention. It may be used both for the blood serum and the cerebro-spinal fluid. To 0·1 cubic centimetre of clear fluid is added 0·5 cubic centimetre of a 10 per cent. solution of butyric acid in physiological saline; the mixture is heated to boiling, 0·1 cubic centimetre of 4 per cent. sodium hydrate is then added, and the mixture again heated to boiling. If the reaction is positive peculiar light greyish flocculi appear within half an hour, and often within a couple of minutes. Noguchi holds that his reaction is given only by globulin, and especially by the changed form of globulin present in syphilitic and parasyphilitic cases. The great theoretic interest of this fact lies in the recent discoveries that what are provisionally called the Wassermann antibodies are without doubt globulins; in fact, they have been demonstrated to be euglobulins. It may be said that the Wassermann reaction depends on an increase of some special form of euglobulin normally present in the blood serum and cerebro-spinal fluid, and in this euglobulin is contained the antibody responsible for the positive reaction in that test. Noguchi claims that his method shows this increase better than any other. He found it positive in 37 cases of general paralysis out of 43. Dr. Ernest Jones has obtained it in all of 15 cases of that disease, and in no other, except gummatous meningitis and diffuse cerebro-spinal syphilis. Recently Gay and Fitzgerald have published their results with Noguchi's test in 33 cases. In eight cases of general paralysis it was positive, in one of diffuse cerebro-spinal syphilis, and in 13 out of 14 cases of syphilitic meningitis.. It was negative in two cases of congenital syphilis and in eight non-syphilitic cases. Dr. Ernest Jones concludes that while Noguchi's reaction is of less significance than the Wassermann reaction in distinguishing between general paralysis and cerebro-spinal syphilis, it is of the greatest value in establishing a diagnosis between general paralysis and non-syphilitic mental affections.

MILK ADULTERATION.

A fortnight ago we recorded the infliction of a heavy fine upon a dairy company for diluting its milk. Two other serious charges, one being of a similar nature and both connected with the sale of milk, came before Mr. Cluer at the Old-street police-court on the same day last week and were dealt with by exemplary sentences, the magistrate observing to one of the defendants, who complained that trade was so bad that the business was "starvation" for him, that it was rather one of starvation for the babies who had to drink such milk. In this instance the summons was for selling milk containing 19 per cent. of added water, and a previous conviction for an offence of the same character in last December was proved. The offender, James Bright, trading at Bethnal Green, was fined £40, with the alternative of three months' imprisonment. In the other case the borough council of Shoreditch prosecuted the Great Western and Metropolitan Dairies Company who were the defendants to a charge of selling milk from which 32 per cent. of the requisite quantity of butter fat was absent. Against the company two recent previous convictions were proved, obtained respectively by the Camberwell and Bermondsey borough councils, and Mr. Cluer imposed a penalty of £50 with 10 guineas costs. The repeated punishment of the same defendants in cases of milk adulteration and the instances mentioned of convictions of the same company in three different boroughs, all inhabited by a poor population, support the suggestion made in The Lancet of June 19th, to the effect that the proposed licensing of milk-dealers with a view to the prevention of infectious disease might carry with it the possible forfeiture of licences in cases of adulteration, and that special provision should be made so as to render this an effective punishment and preventive measure in the case of companies.

THE RARITY OF CONGENITAL DEFORMITIES IN EGYPT.

Professor F. E. Madden, of the Egyptian Government School of Medicine, has sent to us an interesting note on the rarity of congenital deformities in Egypt, in which he writes: "I have recently operated on an Egyptian boy with cleft palate, a fact not remarkable in itself were it not that this is the first operation for this condition I have performed in Kasr-el-Ainy Hospital during nearly 11 years' general surgical work. Nor are there any children's hospitals in Cairo where such cases might be treated unbeknown to us. With the truly awful struggle for existence amongst Egyptian children, it may well be that infants starting life with such a handicap would be the first to perish, but if the condition existed to any extent I think we would meet with it more frequently than we do. It is interesting to note also that of the many thousands of ancient Egyptian bodies which Professor G. Elliot Smith has unearthed and examined there has only been one case of cleft palate in the whole series. In the third Bulletin of the Archæological Survey of Nubia, published by the Survey Department in Cairo, 1909, this unique specimen (found by Dr. D. E. Derry) is thus described: 'In Grave No. 91 was found the skeleton of a young woman, over 20 years of age. She differed from the large majority of the women in this cemetery in being orthognathous; but though the margins of her nares were sharp, the nose was rather flat and broad, and the mandible distinctly Negroid. Her skull is of special interest, as it exhibited an extreme form of cleft palate ; a wide gap extends from the posterior margin of the palate to the posterior edge of the premaxilla in front. The deficiency measured 23 by 24 millimetres, and is symmetrical: in other words the palatal processes of the palate and the superior maxilla are quite rudimentary.' This patient lived between the fourth to the sixth centuries A.D., and her skull now forms one of the most interesting exhibits in our Anatomical Museum, eloquent evidence of one of the very few mistakes made by Nature in the shaping of primitive uncivilised man. The only case of talipes met with by Professor Elliot Smith among the ancient Egyptians was described by him in the *Bulletin de l'Institut Égyptien*, 5e Serie, Tome 1, pp. 45–47. *The left foot of King Siptah*, one of the last Kings of the XIXth Dynasty, was found to be 'distorted in the manner known as talipes equino-varus.' The rarity of congenital deformities generally among the *modern* Egyptians is well seen by referring to the statistics of the Kasr-el-Ainy Hospital, compiled by Dr. H. B. Day, the medical registrar, for the last two years. In 1907, with a total of 2630 surgical admissions, the only congenital deformities were 5 hare-lips, 2 talipes, 2 cases of imperforate anus, and 1 of extroversion of the bladder; while in 1908, of 2702 admissions, there were 3 hare-lips, 2 cases of imperforate anus, 1 of hypospadias, 1 of undescended testicle, and 1 of meningo-encephalocele." Professor Madden considers it to be impossible to endeavour to explain this rarity of congenital defects in Egypt, unless the time-honoured scapegoat of our too modern civilisation be invoked to account for their frequency in other countries.

FLIES AS A NUISANCE.

THAT flies can convey infection is undoubted, but the question of whether or no they convey the infection of summer diarrhœa has been stated by Sir Shirley Murphy to be still unsettled.[1] But that flies are a nuisance and an annoyance, that they may come straight from a dung-heap or an even worse locality and settle on articles of food or fall into milk or other fluids, is certain, and, moreover, at least one species, Stomoxys, inflicts a very painful bite. These facts give special interest to some preliminary reports to the Local Government Board which are now before us on Flies as Carriers of Infection. The final report on the whole subject will be written by Dr. S. M. Copeman and will appear at a later date. The three reports published comprise one by Mr. E. E. Austen on how to distinguish the differing species of flies commonly found in houses—namely, Musca domestica, Stomoxys calcitrans, and Homolomyia canicularis. The difference in the sexes is shown by the relative position of the eyes to one another. In the female they are wide apart, but in the male they are close together. The three species are easily distinguishable by the arrangement of the veinings on their wings, a point well shown in the illustrations supplied with the report. Mr. Austen also supplies a note on the various kinds of flies received by him for examination during the summer and autumn of 1908. Musca domestica largely outnumbered all other kinds received, but it is worthy of mention that some specimens were received of Protocalliphora groenlandica, a species which is not ordinarily found in dwellings. Mr. Austen says that its larvæ are evidently imported in sacks of bones received at glue and size works, and that possibly it breeds in these works. It was found in numbers on August 10th in the kitchen of a London County Council school about 150 yards from works of this description. The last report is by Mr. J. P. Jepson on the Breeding of Musca Domestica during the winter months, and the inquiry was carried on in the Quick Laboratory, University of Cambridge. The conclusions were that flies do breed in favourable circumstances such as they are placed in during mild winters, but that whether they do so in ordinary circumstances is uncertain, although it is probable that such is the case in warm places. On the whole, it would appear from the various researches on flies which have been undertaken of late—for instance, those by Dr. W. H. Hamer[2] for the London County Council, and by Dr. J. T. C. Nash[3]—that the poet, be he William Oldys or another, was in error when he sang—

> "Busy, curious, thirsty fly,
> Drink with me and drink as I."

It would be more reasonable to invite the fly to a separate drink of formalin.

THE GLOUCESTER ROYAL INFIRMARY.

THE King, on the occasion of his visit to Gloucester on June 23rd, was graciously pleased to give his permission for the Gloucester General Infirmary to be known henceforward as the Gloucester Royal Infirmary, "in recognition of the admirable work done by those responsible for its management, and the devoted and successful efforts of its staff in the prevention and alleviation of human suffering." Mr. E. Dykes Bower, senior surgeon to the infirmary, informs us that the last occasion when Gloucester received the honour of a Royal visit was on July 24th, 1788, when George III., with the Queen and the Princesses Augusta and Elizabeth, visited the hospital and, as minuted in the infirmary books, "expressed their approbation of the attention of the Faculty to the health of the patients, and of the cleanliness and good order with which the House appeared to be conducted." The infirmary was founded in the year 1755, when King George II. presented 9200 feet of rough oak timber from the Forest of Dean for use in the fabric of the new building. We congratulate the Gloucester Royal Infirmary upon the well-won honour now conferred upon it by the illustrious descendant of its first Royal benefactor.

THE ABUSE OF HIGH-FREQUENCY CURRENTS.

IN view of the use, or rather abuse, to which high-frequency electrical treatment has been put during recent years, it takes a certain courage to come forward with a contribution bearing on this particular therapeutic measure. That "high-frequency" methods have obtained such a malodorous reputation among some members of the medical profession is not the fault of the methods themselves. The greatest curse has been the fact that the apparatus is imposing to the non-expert eye, it makes a lot of noise, and there are plenty of sparks and violet brush discharges, which can be allowed to come into momentary contact with one's person with comparatively trifling results; and when applied in the usual way the patient experiences no unpleasant sensations from them, with possibly a few exceptions. Perhaps no combination of circumstances than those just detailed could have been better devised with the object of fitting in with the schemes of unskilled and more or less unprincipled persons posing as experts in electrical treatment. One of the least pleasant features of the situation is the readiness with which many qualified medical men, who ought to know better, have supported institutions throughout the country by sending their patients to them for a course of treatment while making no inquiry as to the methods of procedure of those actually responsible for the treatment. The possibility of high-frequency currents doing good in certain cases has never been doubted by those who were in a position to form an opinion on the matter, but, with what has taken place on many occasions in their minds, few medical men with real knowledge have been tempted to express themselves in any way on the subject. The time would seem opportune, however, to do something to appraise the value of high-frequency treatment with an approach to accuracy, and on this account we would draw attention to a paper in this issue by Dr. C. F. Bailey of Brighton. Dr. Bailey has brought forward his arguments in a very straightforward and concise way and quotes several cases which appear to bear out his contentions. A great feature of high-frequency treatment is that electrical energy alone seems to be the ruling factor. In all other electrical methods the action is complicated by chemical processes, the products of electrolysis, migration of ions, and so on, and this differentiation makes a study of the action of high-frequency currents on living tissues one of exceptional interest.

THE PRACTICAL VALUE OF THE ESTIMATION OF THE COAGULATION-TIME OF THE BLOOD.

THE method of estimating the coagulation-time of the blood introduced by Sir Almroth E. Wright, and the practical conclusions obtained by him in regard to the influence of calcium salts and citric acid upon the coagulation-time, have been criticised in some recent papers by Dr. T. Addis.[1] Dr. Addis claims that the method he employs is more accurate than that of Sir Almroth Wright, and that calcium salts and citric acid do not effect any change in the coagulation-time of the blood. Wright's method and its value have been exhaustively studied in an interesting paper published in the *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, Band XX., p. 218, by Dr. Wolfgang Denk and Dr. J. Hellmann, and we recommend our readers to study this interesting communication. Its authors review the various methods employed to estimate the coagulation-time and point out the importance of certain details of technique—e.g., the effect of variations of temperature, the effect of taking the blood from a vein or from a simple puncture, and the influence of pressure around the puncture whereby the blood becomes mixed with tissue fluids and the coagulation-time considerably accelerated. The object of their research was to examine systematically the coagulation-time of the blood in a variety of conditions in which there was any anomaly of the blood, or in which hæmophilia was suspected, in order to establish the value of routine examination of the coagulation-time as a precautionary measure before operation in surgical cases. They used Wright's method, taking the most rigid precautions to avoid sources of error, and they regard it as the most trustworthy. They insist on the importance of cleaning the finger with ether or benzine, the avoidance of pressure, and the use of a fresh puncture for each examination made. To ensure the temperature being constant the pipettes used in this method are at once placed in a thermos flask containing water at 37° C. They found that in normal persons the coagulation-time showed very little variation, being 2 minutes 30 seconds. The time is accelerated in malignant cachexia and in marasmus. This acceleration is not due to the malignant growth, since 20 observations on cases of malignant disease without cachexia did not show it. They give a remarkable table, showing their observations on 18 cases of various kinds in which the coagulation-time was longer than the normal, including some of hæmophilia and of purpura, in nearly all of which the history showed the occurrence of abnormal and intractable bleeding, either spontaneous or as a sequel of some operative procedure. In two of these cases the coagulation-time was over five minutes, and in nearly all of them it was over three. They confirm the observations of previous workers as to the lessened coagulability of the blood in hæmophilia. They also record observations on the effects of calcium lactate, of milk diet, and of citric acid respectively upon the coagulation-time, and they confirm in every detail the contentions of Wright and his co-workers. They recommend the prophylactic administration of lime salts or serum injections controlled by observations on the coagulation-time before undertaking operations upon bleeders, and further advise that in the after-treatment of patients with normal or accelerated coagulation-time, milk and other agents increasing that coagulability should be avoided. Their observations form a striking confirmation of the results obtained by Sir Almroth Wright by his own methods.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE sixty-eighth annual meeting of the Medico-Psychological Association will be held partly at Wakefield and partly at Leeds. The various committees will meet at the Queen's Hotel, Leeds, on July 21st, and the council will meet on July 22nd at Wakefield Asylum. The council meeting will be followed at 11 A.M. by the annual meeting. At 1 P.M. the members will be entertained at lunch by Professor W. Bevan-Lewis. After lunch the retiring President, Dr. Charles A. Mercier, will introduce Professor Bevan-Lewis, his successor, who will deliver an address, and Dr. A. Helen A. Boyle will give an account of an attempt at the Early Treatment of Mental and Nervous Cases, with Special Reference to the Poor. At 10.30 A.M. on July 23rd the following papers will be read at the Queen's Hotel, Leeds:—Dr. J. R. Gilmour on the Mental Symptoms in Exophthalmic Goitre and their Treatment; Dr. Nathan Raw on a case of Acute Mania relapsing into Unconsciousness lasting Seven Months; and Dr. G. Scott Williamson on the Cerebro-spinal Fluid in General Paralysis and the Nervous Lues. In the afternoon of the same day papers will be read by Dr. G. Scott Williamson on the Bacillus paralyticans; Dr. Ford Roberston on the Experimental Production of General Paralysis; and Mr. L. O. Fuller on Alcoholism, Crime, and Insanity. The annual dinner will take place on Thursday, July 22nd, at the Queen's Hotel, Leeds, at 7.30 P.M. Further particulars may be obtained from the honorary secretary, Dr. C. Hubert Bond, 11, Chandos-street, Cavendish-square, London, W.

THE CAUSES OF CHEYNE-STOKES BREATHING.

THE remarkable form of respiration known by the name of its earliest observers as the Cheyne-Stokes breathing has recently been carefully investigated by Dr. C. Gordon Douglas and Dr. J. S. Haldane, the reader in physiology at Oxford. Cheyne-Stokes or periodic respiration was originally observed by Dr. Cheyne in 1818, and again by Dr. Stokes of Dublin in 1846, but the cause or causes of it are obscure. The alternate movements of inspiration and expiration gradually increasing in intensity or vigour up to a certain point, and then diminishing till they are succeeded by a pause of variable duration, have been attributed to disease of the respiratory centres, to abnormal conditions of the heart, and to disease of the brain, and have been observed in narcotic poisoning, in healthy men at high altitudes, in infants, and in hibernating animals. Lately, Dr. M. S. Pembrey and Dr. R. W. Allen have found that pathological Cheyne-Stokes breathing is abolished by the administration of either oxygen or air containing excess of CO_2. Dr. Douglas and Dr. Haldane in their experiments recorded in the number of the *Physiological Journal* for June, 1909, found that the Cheyne-Stokes breathing could be easily produced experimentally and have taken advantage of this fact in order to investigate the causes of periodic respiration. They found that if apnœa were produced by deep respirations the return to normal breathing was preceded by a phase of Cheyne-Stokes respiration, and that this periodic breathing is produced by periodic occurrence and disappearance of the (indirect) excitatory effects of want of oxygen on the respiratory centres. The want of oxygen may be due to abnormal deficiency in the alveolar oxygen-pressure, or it may be due to effects on the circulation of changes in the breathing, or to both causes combined.

THE AFTER-CARE OF SANATORIUM PATIENTS.

WE have received a paper on the After-care of Sanatorium Patients, read by Dr. H. W. McConnel on June 9th before the Conference held by the National Association for the Prevention of Consumption and Other Forms of Tuberculosis at the Art Gallery, Whitechapel, in connexion with the exhibition which we have already noticed. The paper is of so practical a character that a summary of its chief contents is warranted. It contains the results of the experience of seven years' work at Kelling Sanatorium. The objects of after-care are given as twofold—viz., to arrest relapse and to prevent the development of the loafer. Dr. McConnel points out that the stay at charitable sanatoriums has usually to be curtailed from family reasons or from lack of funds, and that it is as a rule shorter than is desirable. There is, therefore, great scope for advice to the patient in regard to his habits of life and his occupation after leaving the sanatorium. He also strongly insists that there is a great field for measures to prevent the tendency to loaf and to shirk likely to be engendered by the treatment in sanatoriums, unless the objects of the whole scheme are kept in prominence, these being to render patients fit for active work again. The work done by each patient at Kelling is selected by the medical officer and controlled by an overseer. There is also a system of "working patients," who are really ex-patients, eight men and two women, kept on at the sanatorium and selected from the earlier and more favourable cases. They receive their board and lodging free, and in addition a little weekly pocket-money, ranging from 2*s.* to 5*s.* They have more definite working hours than the ordinary patients, and perform more definite forms of work. Another important aspect of after-care is the giving of advice and assistance to patients on leaving. A routine practice is followed at Kelling of considering the condition and circumstances of each case one month after admission. What work the patient is to do on leaving the sanatorium is discussed and the conditions of life in regard to his former occupation are considered, both to see how they can be improved with a view to his return to his former work, or, in case this may be radically unsuitable, with a view to advising him in regard to some change. In addition to this, each outgoing patient receives full advice from the resident medical officer on his departure, with special directions how best to continue his treatment. Each is also advised to have a bedroom to himself, and parents are instructed to bring up their children to some career affording them the best conditions to resist the onset of the disease. In regard to after-care, in the exact sense of the words—viz., care after leaving the sanatorium—an attempt is made to keep in touch with as many of the patients as possible, with the object of giving them advice and help. Each old patient receives a Christmas-card each year, with a request for information as to his health and progress. If no answer is obtained a letter is sent enclosing a stamped, directed card for a reply, and if this fails to bring any reply, enquiries are made, if possible, through someone known to be interested in the case. Dr. McConnel concludes his paper with a strong plea that all sanatoriums should adopt measures for after-care. His recommendations and suggestions are practical, and his paper constitutes a striking record of good and truly philanthropic work.

THE USE OF ELECTRIC CURRENTS FOR THE SEPARATION OF TUBERCLE BACILLI FROM URINE.

WE publish in this week's issue of THE LANCET an interesting research by Dr. Charles Russ upon microbic electric movements and an ingenious application of this property of bacteria to the separation of the tubercle bacillus from urine. It was found that certain bacteria tend to aggregate at one or other electrode when a suitable current is passed through a fluid in which they are suspended, and that when the current is reversed they move in the opposite direction—i.e., towards the electrode the polarity of which now becomes the same as that at which they had previously collected. This aggregation varies with the nature of the electrolyte in the fluid in which the bacteria are suspended. Dr. Russ discusses the cause of this aggregation, and offers as the most probable explanation the suggestion of an affinity between products of electrolysis and the bacteria, leading to their conveyance together with the electrolytically dissociated ion towards the appropriate pole. The fact that a similar aggregation occurs with bacteria killed by boiling is strong evidence against the movement being the result of electrical processes generated in the bacterial protoplasm. Applying this process to the separation of tubercle bacilli from urine, Dr. Russ, after repeated and laborious trials of a number of electrolytes added to the urine, obtained the best results with a mixture of ethylamine, lactic and bromic acids in certain proportions. By using a special form of electrode so arranged as to trap the bacilli when aggregated in its vicinity, he was able to recover tubercle bacilli from urines to which they had been added in relatively small numbers, although attempts to prove their presence by centrifugalisation failed. He suggests, also, that further research on these lines may possibly serve to assist in the specific discrimination of bacteria. In any case, the results so far obtained are highly interesting and promise to have a real practical value, since a trustworthy method for the early detection of tubercle bacilli in urine would be of substantial assistance in diagnosis.

PULMONARY TUBERCULOSIS IN AUSTRALIA.

WE have received a copy of a pamphlet on Phthisis in Australia, with more especial reference to Western Australia, written by Dr. J. H. L. Cumpston, medical officer of the Central Board of Health, Perth, Western Australia, and published by the Registrar-General's Department of that State. A number of statistical tables and diagrams are included, and from an analysis of these Dr. Cumpston concludes that there has been since about 1885 a progressive decline in the death-rate from pulmonary tuberculosis throughout Australia as a whole, and in each individual State with the exception of Western Australia, in which the death-rate declined until 1899, rose again until 1901, since which date it has remained practically stationary. The explanation suggested to account for the maintained death-rate in Western Australia is that it has received contributions from each of the other States, more especially during the sudden increase in its population due to the discovery of gold-fields and to the energetic policy of importing agricultural settlers pursued by the authorities. In support of this suggestion it is shown that in the years 1903-05, more than half of the total cases were in people who had been less than ten years in the State. The highest mortality from pulmonary tuberculosis in Western Australia occurs between the ages of 25 and 35 years. Between 15 and 25 years more females die from the disease than males, while below the age of 15 years and above that of 25 the male deaths are in excess. In Australia the decline in the death-rate from this disease commenced soon after the discovery of the tubercle bacillus, and according to Dr. Cumpston this seems to be the only factor in Australia that can at present be shown statistically to have had any effect. The passing of effective Health Acts cannot be regarded as the cause, since these only date from 1890 in Victoria to 1904 in Tasmania. That there is scope for improvement is shown by the fact that during 1907 the Commonwealth suffered a loss of 2863 deaths from this disease, of which 206 occurred in Western Australia. At the same time the death-rate of the Commonwealth from pulmonary tuberculosis compares very favourably with that of most other countries, being only 808 per 1,000,000 of the population for the year 1905, compared with 1144 for England and Wales for the same year. Dr. Cumpston strongly recommends the prohibition of any patients with this disease from other countries landing at any port within the Commonwealth, in order to prevent them from becoming a charge upon public funds and centres of fresh infection. We are strongly in sympathy with any practical measure directed to the prevention of the spread of this disease, but we deprecate any tendency to treat the unfortunate sufferer as a pariah to be avoided, and a rigid enforcement of such a proposal as that suggested by Dr. Cumpston would be attended with serious hardship and might prevent the acquisition by the Commonwealth of some desirable emigrants with arrested disease.

THE PHYSIOLOGICAL ACTION OF ALLYL ISOTHIOCYANATE.

IN the *Bio-Chemical Journal* for April 26th Dr. E. Wace Carlier describes some aspects of the physiological action of allyl isothiocyanate, a substance which within the past few years has received some attention as a therapeutic agent. In the form of oil of mustard it is widely used as a rubefacient and counter-irritant. It is much more toxic than allyl sulphide, as was found by comparative experiments on animals. It attacks the respiratory system much more powerfully than the vaso-motor, though its effects pass off more quickly from the former than from the latter. Poisonous doses kill by paralysing the respiratory centre, as with allyl sulphide. The expiratory centre seems to be more affected than the inspiratory, resulting in considerable chest inflation. A tolerance is set up for the drug on the administration of repeated doses of the same strength, so that a stronger dose has to be given each time to produce an equal effect. By the first dose the vaso-motor centre is depressed and recovers but slowly, but from subsequent doses it not only recovers more quickly but is less affected and becomes stimulated, so that the blood pressure rises high above the normal. The minimum fatal dose is approximately one-fifth minim per kilogramme of body weight, while that of allyl sulphide is one-half minim, when injected into the jugular vein. Both allyl sulphide and allyl isothiocyanate act in a similar manner upon the organism, the latter being the more powerful. Both paralyse the respiratory and vaso-motor centres, both produce muscular spasms and affect the heart beat, and both lower the body temperature, as is the case with most essential oils. Neither is recommended by Dr. Carlier for internal administration, despite the fact that they are commonly ingested in minute quantities with food. In this connexion it is of interest to note that an introductory paper on the Use of Allyl Sulphide in Tuberculosis, by Dr. Paul Bartholow, appeared in the *New York Medical Journal* for May 22nd.

AT a meeting of the Physiological Society held at Oxford on June 26th, Professor F. Gotch, who presided on the occasion, after speaking in warm terms of Dr. Pavy's life-work, presented to him, in commemoration of the eightieth anniversary of his birth, a silver bowl bearing the following inscription: "Frederick William Pavy, M.D., F.R.S., May 29th, 1909. From the Physiological Society in token of affection and admiration."

Professor Ernest W. White, M.B. Lond., of Betley House, near Shrewsbury, late resident physician and superintendent of the City of London Asylum (1887–1905), has been elected Emeritus Professor of King's College, London (University of London), on retiring from the chair of psychological medicine after 20 years' tenure of the same.

THE King has given permission to Mr. Edward S. Crispin, Director of the Soudan Medical Department, Khartoum, to accept and to wear the Imperial Ottoman Order of the Osmanieh of the Fourth Class, which has been conferred upon him by the Khedive of Egypt in recognition of valuable services rendered by him.

THE London County Council on June 29th expressed its agreement with the report of a departmental committee on the London ambulance service, in favour of the extension of the service of rapid ambulances for non-infectious cases initiated by the Metropolitan Asylums Board.

THE DARWIN CENTENARY.

(Concluded from p. 1870.)

THE celebration of the centenary of Charles Darwin, which took place last week at the University of Cambridge, did not come to a conclusion until Thursday afternoon, by which time we had gone to press. The proceedings, however, on Thursday were every whit as interesting as those of Tuesday and Wednesday.

In addition to the addresses which we published last week the following three addresses were presented by Dr. Norman Moore, Senior Censor of the Royal College of Physicians of London, Sir Henry Morris, President of the Royal College of Surgeons of England, and Dr. Norman Moore, for the President of the Royal Society of Medicine, respectively, to the University of Cambridge on the occasion. They will be read with interest, showing, as they do, the intimate association of Darwinian research with the progress of medicine and surgery, as well as the close connexion between Darwin personally and the medical profession.

The Royal College of Physicians of London to the Chancellor, Masters, and Scholars of the University of Cambridge, greeting:—

We, the President and Fellows of the Royal College of Physicians of London offer you our congratulations on the centenary of the birth of the illustrious Charles Darwin.

We have the honour of association with you in the lives of some of your most famous men of science. Caius and Gilbert and Harvey and Glisson were all Fellows of our College, and each of them was in his time chosen to its highest office.

Our College, founded in 1518, was the earliest scientific society of England. Its Fellows have had a considerable part in the advancement of Natural Science studies, and the collections of our President, Sir Hans Sloane, were the beginning of the British Museum. Thus we belong to the world of Natural Science as well as to that of our own profession, and we have felt profoundly in our particular studies the impulse which the publication of the "Origin of Species" and the subsequent work of Darwin gave to Natural History and to every subject in any way related to it. We admire his generous character as well as his devotion to the elucidation of the problems of Biology, and we join the University most cordially in commemorating so great and so virtuous a man.

We have desired our Senior Censor to present this address to you.

R. DOUGLAS POWELL, President.

June 16th, 1909.

An Address from the Royal College of Surgeons of England to the Chancellor, Masters, and Scholars of the University of Cambridge:—

The Council, Fellows, and Members of the Royal College of Surgeons of England experience in a very special degree a deep sense of gratification in having been honoured by an invitation to send a delegate to the Commemoration by your University of the Centenary of Charles Darwin's birth and the fiftieth anniversary of the publication of his great epoch-marking work "On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life."

We feel a peculiar, indeed an almost personal and certainly a professional, pride in taking part with your great Commonwealth of learning and knowledge as a whole, and with Christ's College and the Faculty of Natural Sciences in particular, in this In Memoriam celebration of one who in so conspicuous and brilliant a manner added lustre to your great and ancient University.

The numerous and intimate personal and family associations of Charles Darwin with the University of Cambridge are equalled by similar connexions with the profession of medicine. We are mindful that his grandfather, the celebrated scientist and poet, Dr. Erasmus Darwin, was a physician at Lichfield, and afterwards at Derby; that his father was a very successful medical practitioner at Shrewsbury; that his only brother was a Bachelor of Medicine of Cambridge; and that his paternal uncle and he himself were intended for the medical profession, and actually studied physic at the University of Edinburgh.

The sciences to which Charles Darwin devoted his life and on which he built his great generalisations are, some of them, ancillary to medicine; and as developed and interpreted by him they transfigured many of the doctrines and classifications of disease, illumined with new conceptions pathology as well as biology, and opened up fresh avenues of thought and new pathways of investigation leading to a more correct and scientific knowledge and practice of the resources of surgery.

To the Museum of our College Charles Darwin presented about 30 valuable specimens of fossil mammalia collected by him during the voyage of the *Beagle*, a fact which may not be generally known.

To the students of medicine, as well as to the students of general biology, Darwin has left on record a caution of the utmost importance, and at no period more than at the present time have they had greater need to be reminded of it. He [illegible] his neglect of [illegible] oved one of the [illegible] ical knowledge and aptitude he would have gained by the practice of dissection would have been invaluable for all his future work; and how the want of these, and his incapacity to draw, had been an "irremediable evil," and that "a great pile of manuscript" which he had made during the voyage of the *Beagle* had in consequence "proved almost useless." Charles Darwin esteemed it a high honour to have been elected an honorary member of the Royal Medical Society of Edinburgh and an original honorary member of the Physiological Society which was founded in London in 1876. By his efforts to forward legislation on the question of vivisection, by his private communications to physiologists and others, and by his letters to the editor of the *Times* "on the right of experimenting on living animals," he showed the righteousness as well as the wisdom of his judgment by denouncing the practice of vivisection for "mere damnable and detestable curiosity," whilst he endeavoured to obtain "justice to science," and gave proof of his willingness to bear his "share of the abuse poured in so atrocious a manner on all physiologists." Though, in his own words, "Hippocrates had taken the wind out of my sails," though when informed of the views on pangenesis of this philosopher of antiquity Charles Darwin admitted they seemed almost identical with his own, and although theories somewhat akin to those of the "Origin of Species" had been advanced by Buffon, Lamarck, and Erasmus Darwin, and the principle of natural selection had been enunciated by Dr. Wells and Mr. Matthews, yet the central hypothesis of the "Origin of Species" came in 1859 as a revelation to the historians of scientific ideas as well as to all the biological specialists then living. Charles Darwin knew that he was regarded as "the greatest revolutionist in natural history of that, if not all centuries," and he naturally yearned for some half dozen great and sound scientists to accept his views, for then he would have no fear of their ultimate success.

And whose were the opinions he most especially valued and "longed to learn"? They were those of J. D. Hooker, Charles Lyell, Huxley, Richard Owen, W. B. Carpenter, Milne-Edwards, and Asa Gray, every one of whom except Sir Charles Lyell had received a medical education and was the holder of a medical degree or other medical qualification. Two of them, Huxley and Owen, had been intimately associated with the Royal College of Surgeons of England, Huxley as a Member of the College and Hunterian professor, and Owen as a Member and Fellow of the College and Hunterian professor and conservator of the Hunterian Museum for many years. Hooker and Huxley were the most sympathetic exponents and staunchest champions of the Darwinian principles, and if Owen never actually expressed a definite opinion of Darwinism he at least inclined to the theory of "natural selection," and conduced to the writing of a letter in which Charles Darwin evinced a candour, a modesty, a tolerance of disagreement, and an indifference to the claims of priority which so supremely characterised him throughout his whole scientific career.

It is interesting to us who are connected with the College of Surgeons to re-call that in 1859 Owen delivered the Rede lecture at Cambridge—his subject being the "Classification of Mammalia"—and that he then received the degree LL.D., thus becoming the recipient of the first honorary degree ever conferred by this University. Also in the same year the remains of John Hunter, the great founder of scientific surgery, the fruits of whose labours will for all time be the chief glory of our College, were removed from the vaults of St. Martin's-in-the-Fields to Westminster Abbey. If, instead of the re-interment of the body—lifeless for 60 years—Hunter could have been restored to life in this world, it is only reasonable to conclude from the opinions expressed in several of his writings that he would have greeted the "Origin of Species" with great delight, and would have given it the readiest and fullest acceptance.

For these amongst other more general reasons does our College, with special zest and gladness, beg to offer to the University our best wishes for the success of these memorial ceremonials, and to thank her for affording us the pleasure and satisfaction of joining with the representatives of the liberal arts and sciences from all parts of the world in this tribute of honour to the name and fame of one of her most illustrious sons.

HENRY MORRIS, President.

The Royal Society of Medicine to the Chancellor, Masters, and Scholars of the University of Cambridge, Greeting:—

We, the President, Fellows, and Members of the several sections of the Royal Society of Medicine congratulate the University of Cambridge on the occasion of the centenary of the birth of Charles Darwin. The glories of your University in Science were already brilliant when this great luminary appeared. Newton, greatest of all men of Science, had explained the order of the Universe, and Harvey, in the Microcosm of Man, had demonstrated the course of the circulation. Gilbert had discovered the magnetism of the earth, Woodward had laid the foundations of Geology, and Ray had taken the first steps in the systematic arrangement of animals and plants, while the whole circle of scientific thought had been influenced by that philosopher of whom your immortal Dryden says—

"The world to Bacon does not only owe
Its present knowledge but its future too"

Amid such a galaxy it might well seem difficult for any orb of equal brightness to shine forth, yet in Natural History and in every science related to it, it may be doubted whether any man, since the time of Aristotle, has had a greater effect upon the course of study than Charles Darwin.

That so many of these your most illustrious men of science have been members of the profession of Medicine is sufficient to show how closely its practice and the investigations of Disease are bound up with every other science, and on this auspicious occasion we and all members of our profession rejoice to remember that the great man in whose celebration you have asked us to take part was descended from two generations of doctors of Medicine. Charles Darwin's mind may be said to have thus inherited that desire—

Rerum cognoscere causas—

which pervades our profession.

In common with the whole world of science we offer you our congratulations and join with you in remembering Charles Darwin with gratitude.

WILLIAM S. CHURCH.

On Thursday morning the Chancellor conferred the degree of Doctor of Science upon numerous famous men of science, many of whom had worked along paths which had been made possible by Darwin's great discoveries and achievements. The particular contributions of most of them to scientific knowledge will be familiar to our readers. When the Congregation was declared open, the Public Orator, Dr. J. E. Sandys, presented those about to receive the degree to the Chancellor in felicitous language, some of the topical remarks displaying very ingenious Latinity and being received by those who were fortunate enough to take the allusions with applause and laughter. The recipients of the degrees were presented in the following order: Prince Roland Bonaparte, Professor Edouard van Beneden, Professor Geheimrat Hofrat Otto Buetschli, Professor Robert Chodat, Mr. Francis Darwin, Professor Karl F. von Goebel, Professor Ludwig von Graff, Professor Richard Hertwig, Professor Harold Hoeffding, Professor Jacques Loeb, Dr. Edmond Perrier, Professor Gustav Albert Schwalbe, Professor Hermann Graf zu Solms-Laubach, Professor Clement Timiriazeff, Professor Frantisek Vejdovsky, Professor Max Verworn, Professor Herman Vochting, Professor Hugo de Vries, Dr. Charles Doolittle Walcott, Professor Edmund Beecher Wilson, and Professor Charles Renne Zeiller.

The presentation of the degree to Mr. Francis Darwin was made the opportunity of a remarkable reception to Darwin's distinguished son, alike on the score of his paternity, of his special scientific work as one of the most distinguished morphological botanists in the world, and of his personal popularity. The presentation of Professor de Vries was also made the subject of special applause, a notable incident, as Professor de Vries' work on mutation has been sometimes, but too narrowly, regarded as antagonistic to Darwin's position.

The Rede Lecture, which followed, was delivered by Sir Archibald Geikie, President of the Royal Society, who addressed his audience upon Darwin as a geologist. After a rapid survey of the position of geology before Charles Lyell published in 1830 his "Principles of Geology," in which the changes of the earth's surface were referred mainly to causes now in action instead of to catastrophic happenings in the past, the lecturer went on to show how Darwin's work had added to our knowledge of the movements of the terrestrial crust, and had furnished at the same time evidence in detail of the influence of various natural agencies in producing profound alterations in the conformation of the globe. He considered that the geology of the "Origin of Species" formed a most valuable contribution to the philosophy of the subject, and he claimed Charles Darwin as a master of geological science.

With the Rede lecture the formal celebration of the Darwin Centenary came to a close, and on all hands it was allowed that the University of Cambridge had honoured herself in the way in which she had done honour to her distinguished son. Of course, an ancient university with its time-honoured stately buildings makes a perfect background for a pageant, while the gorgeous academic costumes, survivals of mediæval habit, turn contemporary mortals for the time being into adequate imitations of their forefathers, and make them fit the landscape as well as adorn it. Full advantage was taken of the natural opportunities of Cambridge for doing justice to such an occasion, while the organisation of the various functions was a model of completeness and smooth working.

THE RESEARCH DEFENCE SOCIETY.

THE annual meeting of the Research Defence Society was held at the rooms of the Royal Society of Medicine, 20, Hanover-square, on June 25th, when Lord CROMER presided and delivered an address to a representative and interested audience. Letters of regret for their unavoidable absence, and of sympathy with the objects of the society, were read from Sir T. Clifford Allbutt, Sir Lauder Brunton, Mr. Sydney Holland, Dr. J. Hughlings Jackson, Sir Henry Morris (President of the Royal College of Surgeons of England), Mr. John Lentaigne (President of the Royal College of Surgeons in Ireland), Sir Frederick Treves, Sir Norman Lockyer, Sir L. Alma Tadema, Lord Robert Cecil, Lord Northbrook, the Duke of Wellington, and Lord Curzon.

Lord CROMER said that the Research Defence Society could not attempt to emulate, and still less to rival, the proceedings of those who thrilled the minds of the public with the imaginary tortures inflicted on a brown dog. "The society does not plaster the railway stations of the metropolis with caricatures of Mr. Stephen Coleridge and his allies. These things must be left to our opponents. On the other hand, our movement must appeal to the great body of our countrymen and countrywomen in the interests of humanity." The speaker very strongly held the opinion that those who believed in vivisection, and not those who opposed it, were acting in the true interests both of the human and of the animal race. It might well be that in some rare instances, physiologists, carried away by the excitement of the struggle in which they were engaged, lost sight of that aspect of the question to which the more moderate members of the anti-vivisection societies very rightly and naturally wished to draw attention. It was well, therefore, that the physiologist, in conducting his experiments, should always remember that he was acting in the presence of the enemy, and that his critics would be little inclined to show him mercy should he inadvertently pass the line which separated the infliction of suffering which was justifiable from that which could not be justified. Nothing was more difficult than to draw this borderline. Every man who went out shooting, hunting, or fishing; every man or woman who wore a fur coat; every lady with the plumage of some beautiful bird in her hat was directly or indirectly the cause of death or suffering to animals. More than this, every individual who ate meat caused not merely animal death but was indirectly responsible for the cruel operations which were performed on sheep and on bullocks in order to render their flesh more tender. If it was justifiable to inflict death and pain on animals in any circumstances, surely the justification assumed the form of absolute proof when death or pain was inflicted in the interests of humanity. If anyone would take the trouble to read the voluminous evidence presented to the Royal Commission on Vivisection, whose report he (Lord Cromer) most earnestly trusted would soon be issued, it would be found that there was not a single alleged case of extreme and unnecessary cruelty brought forward by the Anti-Vivisection Society which did not hopelessly break down under cross-examination. It was very natural that this should be the case, not merely because the fact of a man being a physiologist in no way debarred him from entertaining those feelings of sympathy towards the animal world which were felt by every civilised human being, but because, putting the matter on much lower ground, the struggles of an animal in pain tended to nullify the accuracy of the experiment which was being conducted, and thus rendered abortive the experiment. This point had been clearly brought out in a very eloquent manner recently by that eminent French physiologist, Dr. Charles Richet. It was not pretended that suffering, whether by inoculation or vivisection, was not inflicted on animals, but it was asserted by the society that the suffering was reduced to a minimum—to the irreducible minimum justified by the results which are obtained. The antiseptic method had reduced the mortality in lying-in hospitals from as much as 40 per cent. to 0·2 per cent. It was the direct outcome of the experimental method. "I would ask," continued Lord Cromer, "if the lives of the rabbits sacrificed by Villemin in 1864 and Koch in 1878 are to be weighed for one moment in the balance in comparison with the marvellous discoveries in connexion with tuberculosis made by those eminent physiologists? These discoveries have created nothing less than a revolution in social hygiene, and in this country have reduced the mortality on account of this terrible dis[illegible] 50 per cent. Moreover [illegible] Koch was able to disco[illegible] is possible to ascertain [illegible] reverse. It would be difficult to exaggerate the im[illegible] of this discovery. But perhaps the most striking ins[illegible] that of the application of sero-therapy to diphtheri[illegible] has only to study the figures both in London and in [illegible] be assured of the fact that since the introduction [illegible] toxin the mortality through this terrible disease h[illegible] enormously reduced. Again, as a direct result of the [illegible] mental method, Malta fever has been extinguishe[illegible] naval and military hospitals, Sir David Bruce repo[illegible] almost empty, and the island has become the healthiest of garrisons. Formerly, this severe and dangerous disease accounted annually for 75,000 days of illness. The researches of two eminent American physiologists, Dr. Simon Flexner and Dr. J. A. Jobling, have enabled the mortality from that terrible complaint, cerebro-spinal meningitis, to be reduced by more than 50 per cent. Do not these striking results speak for themselves?" Lord Cromer concluded by referring to the cancer problem, with regard to which bacteriologists were constantly being taunted because they had not yet discovered a cure; and in this connexion he quoted Dr. James Ewing, professor of pathology at the Cornell University Medical College, who said on this subject: "What is the reason why medical science has always branded this field as a barren territory? It is because the method of study by means of animal experimentation was not thought applicable to the subject of cancer. Diphtheria has been cured, because we can reproduce the disease in animals, study its progress under controllable conditions, and test for its cure the antitoxic agents prepared according to the accepted theories of the laboratory. None of these methods was thought applicable to cancer." Professor Ehrlich, the leader of German cancer research, had said that the beginning of [illegible] Ewing [illegible] accordi[illegible] mental method in medical and biological research. "It is to my mind," said Lord Cromer, "almost inconceivable that any body of thinking men and women can hesitate for one moment to sacrifice the lives of a certain number of mice, rabbits, and rats if the least chance exists of eventually finding a remedy for this terrible scourge—a scourge, be it remembered, which not only causes death, the lot of all, but kills the victim under conditions of pain infinitely greater than that inflicted by any experimentalist in his laboratory."

The report of the committee for the year 1908–09, which was read by Mr. STEPHEN PAGET, was as follows:—

Your committee are glad to be able to report that the society has [illegible]

[illegible] course of formation.

In the United States, the work of our society has been followed with [illegible]

[illegible] very favourably [illegible] has been circu[illegible] of the society have attended many debates in London and elsewhere, and the [illegible] ts have also [illegible] ectures have [illegible] lides, by Dr [illegible], Dr. Duke [illegible] such titles as [illegible] of Fighting [illegible]" have been [illegible] ollege, King [illegible] en, London [illegible] Royal Naval Academy, Bognor, Ilford, Chelmsford, Bournemouth, [illegible] ewhere. Several of these lectures [illegible]

[illegible] their life to methods discovered by the help of experiments on animals may be glad to be thus associated with the Research Defence Society. [illegible] com- [illegible] to the [illegible] issue [illegible] great [illegible] delay [illegible] public mind.

Dr. F. M. SANDWITH having read the financial statement and announced the first legacy to the society—namely, a gift of £1000 bequeathed by the late Dr. John Hall—

Sir JAMES DEWAR moved the adoption of the report. He lamented the lack of interest which was taken by the public in the borderland between physiology and chemistry. He instanced the coal tar industry and said that this country little understood what Germany was doing to stimulate the investigation of new chemical products. Each factory had its own laboratory as thoroughly equipped as any English or Scotch University. German firms knew quite well that research of the kind to which he referred, however expensive in the initial outlay, would eventually repay them a hundredfold. The large number of chemical and physiological substances which had thus been produced were of the most serious import to medical knowledge at large as well as to the art of dispensing. The properties of these products had to be examined physiologically as well as chemically, and on these products much of our future well-being might depend. Experimentation upon animals had become an absolute necessity for the future extension of such knowledge. There was no other method of attaining that knowledge. If we were forced to this conclusion it was not because we were unable to sympathise with pain but because of the calls of inevitable duty. He noticed from the annual report of experiments on animals that only 6 per cent of the experiments were made in regard to enzymes and drugs. The percentage of such experiments made in another country would be found to be far larger. He concluded with an earnest plea for greater stimulation of inquiry into the physiological properties of chemical bodies, adding that experimentation on animals must go on in order to obtain knowledge which could not be obtained in any other way.

Sir A. CONAN DOYLE seconded the adoption of the report. He said that it was not science but only common sense that was required to decide whether experiments should be made, and the question whether human beings or animals should be selected for experiment carried with it its own answer. He referred to a lurid picture exhibited at some railway stations, and said that if he possessed the original block from which the picture was made he would leave in all the present details but would have depicted in addition on one side of the picture a poor mother leaning over her child who was dying from diphtheria or some other preventable disease. Under the picture he would put, "Which is it to be?" He might also add these three questions: 1. Which should perish—the lower or the higher organism? 2. Which is better—that one should die, or that tens of thousands should find a mode of life? 3. Which is better—that one should perish painlessly under chloroform or that many should die in the agonies of long-drawn-out disease?

The report was then unanimously adopted.

The Hon. WALTER GUINNESS, M.P., in moving a vote of thanks to the chairman, pointed out the valuable work which the society could do in forestalling the attacks of its opponents, and remarked that Lord Cromer was a most valuable asset to the society not only on account of his great prestige but also on account of the personal interest which he took in the work of the society.

Professor STARLING seconded the motion and the vote was heartily accorded.

The CHAIRMAN then briefly replied and the meeting terminated.

---

[1] The exact number on the day of the meeting was 2560 members and 61 associates, making a total of 2621, of whom 374 are ladies.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 2nd, 1831.

CASE OF HAY FEVER.

To the Editor of THE LANCET.

SIR,—Having noticed in your valuable Journal, some remarks by Dr. Elliotson on *hay-fever*,[1] I beg you to accept the account, or as much of it as I remember, of a case which came under my observation some three or four years ago, during my apprenticeship at Paris. A gentleman called, stating he wished to see my master, as he was suffering from a severe attack of the hay-fever. The term was quite new to my ears, and I thought it must either be the result of fancy or the mistaken name of a complaint. When my master saw him, he found symptoms much resembling slight spasmodic asthma, with tolerably easy expectoration, and a great deal of nervous irritability of the system, the patient appearing to be rather a hypochondriacal subject. He stated that he generally had an attack once a year, about the hay-making season, which lasted a fortnight or three weeks, and that the last seizure occurred suddenly whilst he was travelling from Italy. There was no grass to be seen about the immediate spot, but on proceeding a mile farther he found some people mowing, to which circumstance he immediately attributed the attack. He said that he was always better in a neighbourhood where there was little grass, and never had an attack in the winter. During his passage through Normandy, where the land is chiefly meadow, he had been a dreadful sufferer. The medicine prescribed was infusion of valerian, to which, I believe, a little tr. sennæ was added. He was relieved by this, and continuing to mend on the medicine, at the end of a week stated himself to be quite well. If Dr. Elliotson can glean any instruction from this case, I beg to say he is most welcome to it. I am, Sir, your obedient servant,

AUGUSTUS PRATER.

THE ROYAL SOCIETY CONVERSAZIONE.

THE second conversazione of the Royal Society, to which ladies are admitted, was held in the society's rooms in Burlington House, on Thursday, June 24th, when Sir Archibald Geikie, K.C.B., D.C.L., the President, received a very large number of distinguished Fellows and visitors. The exhibits were again of an interesting character though smaller in number, while certain of them were shown at the previous conversazione held on May 12th. Dr. A. D. Waller, for instance, repeated his demonstration of the electrical variation of the human heart and of the dog's heart on Einthoven's string galvanometer. Professor Norman Collie showed also again the peculiar glow which appears when neon is shaken with mercury, and Professor Sylvanus P. Thompson repeated his experiments illustrating the work done by rubber bands when heated, the contraction being sufficient in some cases to raise a pound weight.

Amongst the other exhibits, mention may be made of Dr. W. N. Shaw's interesting observations by means of experimental balloons of the temperatures and pressures in the atmosphere up to a height of 15 miles. Messrs. Zeiss carried out a very beautiful experiment, in which they projected on the screen by means of a lantern and microscope the images of liquid crystals and of solid crystals formed from them. The most interesting example, perhaps, was that given by cholesterin acetate. Dr. F. W. Edridge-Green showed his spectroscope for estimating colour perception, by which the exact size of portions of the spectrum which appear monochromatic can be ascertained, and their varying size with different persons. A remarkably fine series of photographs of clouds and landscapes taken from a balloon was exhibited by Dr. W. J. S. Lockyer. Professor George H. F. Nuttall and Dr. Seymour Hadwen illustrated in a series of microscope slides the discovery of a curative treatment for malignant jaundice in the dog and for redwater in cattle. The effects of "trypanblau" upon the parasites were shown. It is stated that the results of treatment are so striking that field experiments promise to meet with success, and the observations made upon the parasites in animals undergoing treatment have thrown further light upon their biology. Mr. F. Enock showed some curious living stick insects. When mature these insects attain a length of over four inches and become of a brown colour which harmonises with the brown twig on which they rest. On emerging from the egg they are half an inch in length and quickly stretch themselves along a green twig which they exactly resemble.

There were no lantern demonstrations given in the lecture room, which hitherto have formed an attractive feature of the conversazione on "ladies' night," but the floral decorations on the ground floor and staircases were most lavish and beautiful.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of this society was held at 31, Craven-street, Strand, London, on June 23rd, with Dr. G. A. HERON in the chair. In moving the adoption of the report, which was unanimously agreed to, the Chairman pointed out that the balance to the credit of the society amounted to £3917 and that the total resources of the society on Dec. 31st, 1908, were represented by a sum of £10,613. Taking the cash assets of the society into consideration he calculated it would be possible to pay at very short notice 17*s.* 1*d.* per head of the membership of the society. The Chairman and Council were accorded a vote of thanks for their services, which was passed with acclamation.

The annual report of the Council of the society for 1908 takes the form of a closely printed pamphlet of 84 pages and contains much that is of importance to members of the medical profession, especially in regard to matters referring to libel and slander, negligence or unskilfulness, notification of infectious diseases and births, and professional fees. A special committee of the society on the working of the Midwives Act sent in a report which is included in the annual report of the Council, recommending :—

> That it should be clearly understood that no medical man should be expected to attend on the summons of a midwife unless he chose to undertake such work at the fees guaranteed by the guardians, or others.
>
> That the fees of medical men summoned by midwives should be paid to them in all cases without requiring from them any proof of the poverty of the patients, any necessary inquiry being made by the board of guardians or others, who should pay the fees of the medical practitioners without demur, and then take such steps as they might think fit to recover the fees when the patients were able to pay them.
>
> That when a medical man is summoned by a midwife to operate or attend on a woman in a serious emergency, he should be the judge as to whether or not he should visit the patient again, and, if so, how often, and that for these visits the doctor should be entitled to the usual fees in addition to the fee for the operation or attendance.

A charge of unprofessional conduct against a medical man is particularly difficult to deal with, and the following example of such a case is interesting and instructive. A member of the society was called to see a patient staying at a hotel who was suffering from slight hæmorrhage after tooth extraction. She would not let the medical man take his own course to stop the bleeding, and after wasting about an hour there he did what he could but told the patient he would not come again to attend her. Subsequently, however, the medical man received very urgent appeals from a male friend of the patient, and at last consented to attend on the representation that the patient's life was in danger. When he sent in his account he received a letter from the patient saying that she considered his account not due, inasmuch as he unskilfully and ineffectually attended to her and refused to call when she instructed him to come. If he persisted in his claim she said she would place the matter in the hands of her solicitor. She had, she said, been advised to submit the whole matter to the Council of the Royal College of Surgeons and abide by its decision in the matter. This letter was answered on the member's behalf and no more was heard of the suggestion of unprofessional conduct. Some of the most awkward instances in which advice was sought by members of the society are recorded in the annual report under the heading of professional secrecy, and are naturally connected with questions of pregnancy and venereal disease. The issue of the cases abundantly proves the value to its members of the society.

---

[1] In THE LANCET of June 18th, 1831, a clinical lecture by Dr. Elliotson was reported. In the course of the lecture Dr. Elliotson requested his audience to give or procure him any information respecting "a very extraordinary affection that I have once only had occasion to treat." "It is what is called *hay-fever or hay asthma.*" "The first time I ever heard of this disease was seven or eight years ago." "If the disease really prevails more now than formerly, and we observe it so frequently now not merely because its existence is notorious, this might perhaps be ascribed to the large number of new grasses which have of late years been introduced."

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts, additional to those already announced in THE LANCET, received at the Mansion House or notified directly to us as having been collected on behalf of the Metropolitan Hospital Sunday Fund up to Monday, when the sum paid in was about £28,000:—

MEDICINE AND THE LAW.

Destruction of Infected Articles by Medical Officer.

THE case of Farrell *v.* Longford urban district council, which came recently before Lord Justice Holmes in Ireland, raised an interesting point as to the destruction of infected property by a medical officer of health. It was an appeal from a decision of his honour Judge Curran, K.C., for £20 damages in an action by Mrs. Sarah Farrell against the Longford urban district council for trespass and for burning and destroying clothing, furniture, bedding, and household effects, the property of the plaintiff. Neither the Infectious Disease (Notification) Act, 1899, nor the Infectious Disease (Prevention) Act had been adopted. The plaintiff kept a lodging house, and in April, 1908, a woman who lodged in the house became ill and was pronounced by Mr. N. Mayne, who attended her, to be suffering from cerebro-spinal meningitis. Mr. Mayne sent to Dr. M'Cann, the medical officer of health of the district, a certificate to the effect that the woman was suffering from that disease, and Dr. M'Cann, considering the matter to be of extreme urgency, without notifying either the executive sanitary officer or the sanitary authority, ordered the immediate disinfection of the house and the removal and destruction of all the furniture, clothing, and other articles therein, which order was carried out by the sub-sanitary officer. It subsequently transpired that the case was not one of cerebro-spinal meningitis or other infectious disease. The plaintiff having claimed a sum of £72 for compensation, the defendants denied liability on the ground that the acts complained of were not done by their authority or with their knowledge and approval. The sub-sanitary officer valued the clothing destroyed at £20 6*s.*, and the county court judge gave a decree for £20. From this decision the defendants appealed. Section 137 of the Public Health (Ireland) Act, 1878, provides for the disinfecting of premises by a sanitary authority on the certification of their sanitary officer or other legally qualified medical practitioner. Section 138 provides that the sanitary authority may direct the destruction of bedding, clothing, or other articles and give compensation for the same. It is the sanitary authority and not the medical officer of health who must order the destruction of articles. Section 274 provides that any dispute as to the fact of damage or amount of compensation shall be settled by arbitration in manner provided by the Act, or if the compensation claimed does not exceed the sum of £20 the same may, at the option of either party, be ascertained by and recovered before a court of summary jurisdiction. Lord Justice Holmes in the course of his judgment said: "There are two points in this case. I am disposed to think that there could not be a full delegation of authority to the medical officer, giving him absolute discretion. If that were done it would be a violation of the statute, because the urban district council are an elected body with statutory powers. On the other hand, in a [illegible]ise of authority by the [illegible]itary authority and [illegible]om what the counsel [illegible]hat I might, if I had [illegible] have come to the conclusion that in this case the sanitary authority did adopt the action of the medical officer. But the other point is, that there is a particular method of ascertaining the damages pointed out by the statute, and, as far as I am aware, that procedure is always adopted throughout the country. That method is not litigation, but arbitration, except in cases where a small amount is claimed, when proceedings may be taken before county summary jurisdiction. I do not know if there is any limit of time, but the plaintiff may still be able to proceed by arbitration. I do not, however, decide that question. I therefore reverse the decree and dismiss the action with costs. I think the sanitary authority might very well not levy the costs."

Conviction of an Abortionist.

William Arthur Jones, William John Lidstone, and Caroline Farmer were tried and convicted at the recent sessions at the Central Criminal Court, the first-named for performing an illegal operation upon Beatrice Dean, and the other two for aiding and abetting him. Dean, employed by Lidstone as a domestic servant, was taken by him to Farmer when he found that she was with child, and by Farmer was introduced to Jones, who, under the title of "Dr." Jones, apparently was well known in Walworth. The confessic Dean to the police enabled proceedings to be taken, and Jones being convicted evidence was given that he had once been upon the Medical Register, but had been removed in 1902 after a conviction for a similar offence. There were other indictments against him, but these were not proceeded with, and Mr. Justice Jelf, after observing that Jones was a man whom it was desirable to get rid of for a long time, passed upon him a sentence of ten years' penal servitude. Lidstone, who received a good character from the police, was sentenced to three months' imprisonment in the second division, and Farmer, described as a respectable married woman, was bound over to come up for judgment if called upon to do so.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7520 births and 3801 deaths were registered during the week ending June 26th. The annual rate of mortality in these towns, which had not exceeded 12·6 and 12·3 per 1000 in the two preceding weeks, further declined to 12·1 in the week under notice, and was lower than the rate recorded in any previous week of this year. During the first twelve weeks of the current quarter the death-rate in these towns averaged 14·2 per 1000; the mean rate in London during the same period did not exceed 13·7. The lowest recorded annual death-rates in these towns last week were 4·9 in Ipswich, 5·2 in Willesden, and 5 6 in East Ham and in Devonport; the rates in the other towns ranged upwards, however, to 17·3 in Middlesbrough, 18·6 in South Shields, 19·5 in Great Yarmouth, and 19·6 in Oldham. In London the recorded death-rate last week did not exceed 12·1 per 1000. The 3801 deaths from all causes in the 76 towns last week showed a further decline of 79 from the decreasing numbers in recent weeks, and included 352 which were referred to the principal epidemic diseases, against 393 and 364 in the two previous weeks; of these 352 deaths, 159 resulted from measles, 63 from whooping-cough, 57 from diarrhœa, 34 from diphtheria, 28 from scarlet fever, and 11 from "fever" (principally enteric), but not one from small-pox. The 352 deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·2 in each of the two preceding weeks. No death from any of these epidemic diseases was registered last week in Leicester, Croydon, Oldham, Tottenham, Halifax, or in seven other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·4 in Norwich, 3·9 in Stockton, 4·5 in Salford and in Bootle, and 5·5 in Wolverhampton. The fatal cases of measles in the 76 towns, which had been 186 and 173 in the two preceding weeks, further declined to 159 last week; the fatal cases of this disease caused annual death-rates last week ranging upwards to 2·9 in Stockton-on-Tees, 3·0 in Salford, 3·4 in Norwich, and 5·0 in Wolverhampton. The 63 deaths from whooping-cough showed a further slight increase upon the numbers returned in the two previous weeks, and caused an annual rate equal to 1·5 per 1000 in Middlesbrough. The 57 deaths attributed to diarrhœa exceeded the number in any recent week; the deaths from this cause were proportionately most numerous in Portsmouth and Bootle. The 34 fatal cases of diphtheria exceeded the number in the previous week by six and included five in Manchester and Salford, three in Portsmouth, and two in Hull. The 28 deaths from scarlet fever showed a decline of 27 from the number in the previous week, but included nine in London and its suburban districts and four in Manchester and Salford. Only 11 deaths from "fever" were registered last week in the 76 towns, against 13 and 16 in the two previous weeks. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2228, 2263, and 2445 at the end of the three preceding weeks, had further increased to 2517 on Saturday last; 368 new cases of this disease were admitted to these hospitals during last week, against 305 and 468 in the two preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had steadily declined in the four preceding weeks from 225 to 135, rose again to 155 in the week under notice, and exceeded by 13 the corrected average number in the [illegible] week of the five years 1904–08. The 13 [illegible]ndon directly referred to influenza last week exceeded the number in the previous week by seven. Th causes of 43, or 1·1 per cent., of the deaths registered las week in the 76 towns were not certified either by a regis tered medical practitioner or by a coroner. The causes o all the deaths registered during the week were again dul certified in Leeds, Bristol, West Ham, Bradford, Newcastle on-Tyne, Salford, and in 51 other smaller towns; the 4 uncertified causes of death in the 76 towns included 13 i Liverpool and three each in Birmingham, Gateshead, Sout Shields, and Handsworth.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 926 births and 45 deaths were registered during the week ending June 26th The annual rate of mortality in these towns, whic had been equal to 16·3, 14·5, and 15·5 in the three pre ceding weeks, declined to 12·7 in the week under notice During the first twelve weeks of the current quarter th death-rate in these Scotch towns averaged 16·2 per 100 while in the 76 large English towns the mean death-rat during the same period did not exceed 14·2. The death-rate last week in these Scotch towns ranged from 8·5 and 10· in Perth and Aberdeen, to 18·3 in Leith and 19·7 i Dundee. The 454 deaths from all causes in the eigh towns showed a decrease of 100 from the number returne in the previous week, and included 54 which were re ferred to the principal epidemic diseases, against 55 an 56 in the two previous weeks. These 54 deaths were equa to an annual rate of 1·5 per 1000, scarcely differing fro the rates in recent weeks; the mean death-rate last wee from these principal epidemic diseases in the 76 large Englis towns did not exceed 1·1 per 1000. Of the 54 death from these epidemic diseases in the Scotch towns, 1 resulted from diarrhœa, 17 from whooping-cough, eigh from measles, six from diphtheria, and five from "fever, but not one either from scarlet fever or small-pox. Th 18 deaths attributed to diarrhœa in the eight towns exceede the number in any recent week, and included nine in Glasgow three in Dundee, and two in Edinburgh. The fatal cases o whooping-cough, which had declined in the four precedin weeks from 40 to 18, further fell last week to 17, of which eigh occurred in Glasgow, five in Edinburgh, and four in Aber deen. The eight deaths from measles showed a decline o five from the number in the previous week, and include four in Paisley, against 10 in the preceding week. Th six fatal cases of diphtheria, of which two occurred i Aberdeen, exceeded the number in the previous week by tw Five deaths in the eight towns were referred to "fever, of which two certified as tpphus occurred in Dundee, on each of cerebro-spinal meningitis in Edinburgh an Aberdeen, and one of enteric in Glasgow. The deaths referre to diseases of the respiratory organs in the eight town which had steadily declined in the five preceding week from 109 to 73, further fell to 64 last week, and wer three below the number in the corresponding week of la year. Of the deaths in the eight towns last week, 1 resulted from violence, including six in Glasgow and thre in Edinburgh. The causes of eight, or 1·8 per cent., o the deaths in the eight towns last week were uncertified in the 76 English towns the proportion of uncertifie causes of death last week did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had bee equal to 18·7 and 15·7 per 1000 in the two precedin weeks, rose again to 19·6 in the week ending June 26t During the first 12 weeks of the current quarter the deat rate in the city averaged 21·1 per 1000, whereas th mean rate during the same period did not exceed 13· in London and 15·9 in Edinburgh. The 150 deaths o Dublin residents from all causes registered last week showe an increase of 20 upon the low number in the previous week and included eight which were referred to the principa epidemic diseases, against nine and ten in the two precedin weeks. These eight deaths were equal to an annual rate o 1·0 per 1000, the death-rate from these epidemic disease in the same week being 1·1 in London and 1·5 i

Edinburgh. Of the eight deaths from these epidemic diseases in Dublin last week, five resulted from whooping-cough and three from diarrhœa, but not one either from measles, scarlet fever, diphtheria, "fever," or small-pox. The fatal cases of whooping-cough showed an increase. The 150 deaths at all ages included 31 of infants under one year of age and 33 of persons aged upwards of 60 years; the deaths of infants considerably exceeded the numbers in recent weeks. Six inquest cases and three deaths from violence were registered during the week; and 62, or 41·3 per cent., of the deaths occurred in public institutions. The causes of two, or 1·3 per cent., of the deaths in the city last week were uncertified either by a registered medical practitioner or by a coroner; in London the causes of all but one of the 1125 deaths last week were duly certified, as were all but one of the 81 deaths in Edinburgh.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel R. I. D. Hackett, Administrative Medical Officer at Bordon, and Lieutenant-Colonel C. R. Tyrrell, Staff Officer to the Principal Medical Officer, Eastern Command, exchange places on the foreign service roster.

ROYAL ARMY MEDICAL CORPS SCHOOL OF INSTRUCTION.

Major Charles C. Fleming, D.S.O., R.A.M.C., to be Instructor, vice Major J. D. Ferguson, D.S.O. (dated June 13th, 1909).

ROYAL NAVAL VOLUNTEER RESERVE.

The undermentioned has been appointed Surgeon: Albert James Gilbertson (dated June 24th, 1909).

TERRITORIAL FORCE.

Infantry Battalions.

5th Battalion Loyal North Lancashire Regiment: Surgeon-Captain Henry J. Taylor, from the 2nd Volunteer Battalion, The Loyal North Lancashire Regiment, to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Royal Army Medical Corps.

2nd London (City of London) Field Ambulance: Reginald Ernest Bickerton to be Lieutenant (dated April 13th, 1909).

3rd London (City of London) Field Ambulance: Captain Hubert C. Phillips resigns his commission (dated May 8th, 1909). Bernard Elwell Potter to be Lieutenant (dated May 12th, 1909).

6th London Field Ambulance: Edward Pigott Minett to be Lieutenant (dated May 18th, 1909).

2nd North Midland Field Ambulance: Albert John Riddett to be Lieutenant (dated April 29th, 1909).

3rd North Midland Field Ambulance: George James Smith Atkinson to be Lieutenant (dated March 8th, 1909).

2nd South Midland Field Ambulance: Samuel George Webb to be Lieutenant (dated May 19th, 1909).

2nd Northumbrian Field Ambulance: George Reginald Ellis to be Lieutenant (dated May 1st, 1909). The undermentioned officers to be Captains (dated May 8th, 1909): Lieutenant Henry C. Pearson and Lieutenant Duncan A. Cameron.

3rd West Riding Field Ambulance: Lieutenant James Mackinnon, from the 1st West Riding Field Ambulance, to be Lieutenant (dated April 26th, 1909).

1st Northern General Hospital: To be Major whose services will be available on mobilisation: Robert Alfred Bolam (late Lieutenant, 9th Battalion, The Durham Light Infantry), with seniority next below Major W. G. Richardson (dated March 30th, 1909).

Sanitary Service: To be Captain whose services will be available on mobilisation: William Butler (dated June 5th, 1909).

1st South Midland Mounted Brigade Field Ambulance: Donald Buchanan to be Lieutenant (dated May 8th, 1909).

1st Home Counties Field Ambulance: George Potts to be Lieutenant (dated Feb. 11th, 1909).

1st South Midland Field Ambulance: Major Arthur R. Badger resigns his commission (dated June 4th, 1909).

5th Southern General Hospital: The undermentioned to be officers whose services will be available on mobilisation (dated July 21st, 1908):—To be Lieutenant-Colonels: Claude Clarke Claremont, Charles Plumley Childe, Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel George Gordon Sparrow (late 2nd Hampshire Royal Garrison Artillery (Volunteers)), Retired List; Harry Wynter Shettle. To be Majors: John Robert Stevenson Robertson (late Surgeon; Army Medical Department), Arthur Vernon Ford, John Phillips, John Rushworth Keele, Norman Elliott Aldridge, Charles Frederic Routh, William Prior Purvis, and Howard Percy Ward. To be Captains: Thomas Arthur Munro Forde, Samuel Goss, George Hebb Cowen, William Patrick McEldowney, Charles Archibald Scott Ridout, John Temple Leon, Harold Burrows, John Henry Pearson Fraser, John Lister Wright, Edward James Davis Taylor, Thomas Holmes, John William Gregory Kealy, Samuel Hughes, Charles Howard Saunders, William Patrick O'Meara, Rolland Atkinson Dove, Alfred William Power, John Tiley Montgomery McDougall (late Surgeon, Royal Navy), Charles Lamplough, and Montague Harold Way.

For Attachment to Units other than Medical Units.—Surgeon-Major William B. Mackay, from the 7th Battalion, The Northumberland Fusiliers, to be Major, with seniority as from August 1st, 1903 (dated April 1st, 1908). Surgeon-Captain Philip John Le Riche, from the 2nd Volunteer Battalion, The Royal Sussex Regiment, to be Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Attached to Units other than Medical Units.—Lieutenant James A. Gibson resigns his commission (dated April 12th, 1909). Captain Richard J. Swan resigns his commission (dated May 3rd, 1909). Lieutenant John E. Simpson to be Captain (dated May 11th, 1909).

THE BIRTHDAY HONOURS.

The list of Birthday Honours includes the names of Lieutenant-Colonel W. B. Leishman, R.A.M.C., who has received a knig[illegible] I.M.S., [illegible] Commar[illegible] Whitehe[illegible] Colonel de Burgh Birch, A.M.O., West Riding Division, Territorial Force, who receive Companionships of the Bath; and of Lieutenant-Colonel Robert Neil Campbell, I.M.S., Officiating Inspector-General of Civil Hospitals in Eastern Bengal and Assam, who receives a Companionship of the Order of the Indian Empire. The *London Gazette* of *June 25th contains the announcement of the appointment of* Colonel Charles Edward Harrison, honorary surgeon to His Majesty, Brigade-Surgeon-Lieutenant-Colonel, Grenadier Guards, as a Commander of the Royal Victorian Order.

Correspondence.

"Audi alteram partem."

MALARIA PREVENTION AT MIAN MIR.

To the Editor of THE LANCET.

SIR,—I see by your issue of June 26th that Major S. P. James, I.M.S., and Captain S. R. Christophers, I.M.S., have not "undertaken the trivial task of replying in detail to each of the criticisms brought forward by Professor Ross," but endeavour to escape from Mian Mir in a cloud of generalities about malaria in India. Permit me to pin them to the point, which is this: whether Major James's recent statements at the Bombay Medical Congress regarding the failure of the operations at that station are true or not true. On a previous occasion these gentlemen neglected the same "trivial task of replying" to the criticisms of Colonel G. M. Giles, Captain E. P. Sewell, and myself on the same subject, and now I see that they repeat all their own inaccuracies about Mian Mir witho[illegible] the complete refutations [illegible] H. Hamilton and Colonels [illegible] D. Rowan, and J. Shearer. [illegible] take this trivial task I feel justified in saying that the whole of their original work at Mian Mir was badly conceived and badly executed, and that it showed little evidence either of knowledge of practical malaria prevention, or even of a genuine intention to obtain success.

With regard to Major James's paper at the congress, the criticisms of the five administrative medical officers mentioned above can, I think, be put in the form of the following series of questions: 1. Is it not true that, owing to exceptional rains, Mian Mir was flooded for weeks last August, and that an epidemic of malaria was raging in the surrounding country? 2. Why exactly did Major James visit the station, after long absence, a few weeks after the floods, at the precise moment when the mosquitoes and the malaria were sure to be exceptionally prevalent in spite of the admittedly partial measures which had been taken against them? 3. Why, in his paper, did he omit to make any reference either to the floods or to the epidemic? 4. Why did he call the station an "arid desert" when it contains many wells and even irrigated gardens? 5. Why did he say that it had been reduced to the "verge of bankruptcy" by the anti-malarial measures, when these had really formed only a small part of the local expenditure? 6. Why in his statistics did he take only a group of years which show, apparently, the worst results? 7. Why did he vitiate them still further by including the statistics of Fort Lahore, which was the unhealthiest spot in the neighbourhood and was not included in the anti-malarial operations? 8. Why did he not state how many of the children found infected by him had only recently come to the station? 9. How does he explain finding infection in the enormous proportion of seven out of ten men of the Gloucester Regiment, taken "more or less at random," when, as Colonel Forman has ascertained, the regiment did not really suffer much? 10. How does he explain the discrepancy between his statements and those of Colonel Rowan, the principal medical officer?[1] 11. Why did he say that the success of mosquito-destruction operations elsewhere (Ismailia) had been "reported on evidence that will not bear criticism and is often ridiculous," without explaining his reasons and without inspecting the place (which is *en route* to India)? 12. Why has he not replied before to these criticisms?

The bulk of the letter by Major James and Captain Christophers consists merely of an abstract discussion, possessing neither depth nor novelty, of the old, old theme of quinine *versus* mosquito reduction. After all, the world judges by results. While, on the one hand, brilliant practical successes have been won by those who have loyally followed the new ideas; on the other hand, Major James and Captain Christophers have nothing to show but a series of philosophical reflexions—and a failure. Yet no men during the last ten years have had greater opportunities.

The position has been well put by Colonel Rowan, who writes: "Should Major James have any suggestions to offer (regarding Mian Mir) that are likely to be more effective than the anti-malaria measures already adopted, they will be most welcome, but it appears to me that he incurs a grave responsibility by attempting to discredit methods which have already, both in Mian Mir and elsewhere, been followed by a large measure of success."[2] I have not heard that Major James has made the required suggestions.

In the meantime, I keep the authors to their statements about Mian Mir. That is the centre of their position—though I perceive they are already endeavouring to make a strategic movement away from it. The Mian Mir bogey has been used long enough to terrorise malaria prevention throughout India—and elsewhere. It must now verify itself or vanish. Frankly, I do not think that Major James can substantiate his statements made at the Bombay Medical Congress. At any rate, until he attempts to do so, I propose to postpone the trifling task of discussing his more general, but, I think, equally fallacious, conclusions.

I am, Sir, yours faithfully,

University of Liverpool, June 28th, 1909. RONALD ROSS.

PS.—Those who wish to compare theory with practice should read the address by Colonel Gorgas in the Journal of the American Medical Association for June 19th, 1909.

To the Editor of THE LANCET.

SIR,—I was present at the Bombay Medical Congress in February, and heard the attack by Major James and Captain Christophers on Professor Ross's methods of malarial prophylaxis as illustrated by the "failure" in Mian Mir, together with the subsequent discussion. That I was startled goes without saying, for my experience—no small one—had convinced me that Ross was right and that the problem which confronted us was not what we had to do and how to do it, but how we could succeed in awakening apathetic authority and induce it to provide the wherewithal to combat a disease which, from both the humanitarian and economic points of view, was of enormous importance. In days gone by I knew Mian Mir and I had watched with considerable interest the progress of the anti-malarial measures in that insalubrious cantonment from their inception down to the present time. Immediately after hearing Major James's paper I made careful inquiry from competent men on the spot, amongst them Lieutenant-Colonel H. D. Rowan, R.A.M.C., who for three and a half years (including 1908) was senior medical officer at Mian Mir; and I also made a comparative analysis of the incidence of malaria in other stations (e.g., Bombay) for the year 1908, which was an exceptionally bad year for malaria all over India, so much so, indeed, that at Cawnpore and elsewhere the railway companies were well-nigh crippled for want of *personnel*. I have been travelling much since then, both by land and sea, and it is only now that I have seen the further attack on Ross in your issue of April 3rd. Hence this belated communication. Your special correspondent in that article says: "In this opinion (i.e., the failure of Ross's methods in Mian Mir) Major James *feels sure* that he will be supported by medical officers at Mian Mir who were able to observe the terrible havoc, &c." Does he? Then all I can say is, that Major James in this, as in other respects, has jumped at an unwarrantable conclusion. Far from this being so, these medical officers without exception dissent emphatically, and no one more so than Lieutenant-Colonel Rowan, an officer of wide experience and one who knows far more about Mian Mir than Major James or any other man, and who, moreover, has made a special study of malarial incidence in that cantonment.[1] In a communication before me Rowan says:—

> I have no hesitation in saying that James's statistics are unfairly adverse to Mian Mir and cannot be relied upon, and this for the following reasons: 1. They are admittedly very different from the returns rendered by the hospital. 2. They cover only a period of five years. 3. They include Fort Lahore. 4. Figures for 1908 are for 11 months only. 5. In 1908 the epidemic of malaria throughout the Punjaub was of exceptional severity.

Permit me very briefly to comment on these points. If Major James relies upon statistics at all—and he does—surely it would be more in accord with the fitness of things if he adopted the carefully compiled official figures and not some hypothetical data evolved from his own inner consciousness, and based on a few scattered personal observations extending over a few days during a flying visit to Mian Mir? The anti-malarial measures were begun in 1904–05, and "it is, therefore, ludicrously unfair to attempt to demonstrate the effect of these measures by comparing the figures of 1908 with those of 1904 and the intervening years" (Rowan). Obviously the comparison should have been made with the quinquennium, 1899–03.

Fort Lahore is one of the most pestilential spots in India; it is some four miles from Mian Mir, and in 1908, for the first time, its vital statistics were, by order, included in those of Mian Mir. The figures for the two places 1903–07, average admissions per 1000 malaria and simple continued fever, were: Mian Mir, 544; Fort Lahore, 891. Yet Major James asserts that the inclusion of the latter favours the former. He strikes an average for December, 1908, on the previous 11 months, ignoring the fact that this month is one of the healthiest in the year. Clearly this is fallacious. If malaria was epidemic everywhere surely it is unreasonable to expect that Mian Mir should wholly escape?

As I have said, the anti-malarial measures were begun actively in 1904, and I may add that they were admittedly limited and partial, nor did the Government give a rupee towards them; every penny had to be found from the funds of a semi-bankrupt cantonment. Yet here are the results, the figures being admission *ratios* per 1000 of strength British troops: 1878–82, 1960; 1883–87, 1524; 1888–92, 1088; 1893–97, 981; 1898–1902, 925; 1903, 1030; 1904, 587; 1905, 425; 1906, 490; 1907, 177; 1908, 537, malaria only (includes Fort Lahore).

Is further comment necessary? Hardly. I personally have not the smallest hesitation in saying that if the Government will give the cantonment of Mian Mir £1000 per annum

---

malaria can be practically abolished from it. Major James and his coadjutors have, in my opinion, been guilty of a very grave scientific crime in thus unwarrantably attacking proven prophylactic measures. In India our whole difficulty has been to *impress upon a lay bureaucracy the necessity of giving effect* to the great discovery of Ross, so far with but very indifferent success. Opposition from without we are accustomed to, but when it comes from within our own ranks, the mischief accruing may not only undo the work already accomplished but may take years to remedy. Dealing as we are with by far the most important factor in the development of tropical and subtropical countries, it seems to me that with existing evidence and experience available, Major James and Captain Christophers should have been very sure of their facts before venturing to enunciate their conclusions. Their whole attack *is unwarranted and unwarrantable; their "facts" are* fallacies; their data false. They have, in my opinion, done incalculable harm; for it is an easy matter to make an assertion but a difficult thing to refute it. Already the effect is apparent in the lay press and elsewhere, and it is certain that with the prevalent procrastination of the East, the awakening which we had fondly hoped was at hand, will now be indefinitely postponed. I for one should not care to bear the responsibility they have so lightly assumed.

I am, Sir, yours faithfully,

R. H. FORMAN,

Colonel, R.A.M.C.; P.M.O. Bombay Brigade.

At Sea, June 8th, 1909.

PURULENT CONJUNCTIVITIS IN INFANCY.

To the Editor of THE LANCET.

SIR,—Those who continue to call the conjunctival inflammation of infancy by the antiquated, inaccurate, meaningless term "ophthalmia neonatorum" may be reminded of a wise saying of Lord Bacon's—namely, "*It is the nature of man, to the extreme prejudice of knowledge, to delight in the spacious liberties of generalities.*" In no department of medicine does a more illogical conservatism prevail, so far as terminology is concerned, than in that of ophthalmic surgery. "Yes, ophthalmia neonatorum is wrong," is the argument, "but then, you know, it has been sanctified by use." Again, much is *made of the statement that the term is useful as a generic* one, implying by this that an infantile conjunctivitis which can be caused by more than one micro-organism had better be described as, not what it is, a conjunctivitis, but as an ophthalmia, which it is not. Thus, to the extreme prejudice of knowledge, a spacious generality is indulged in, to which, as I have frequently observed, much of the confusion in, and the deplorable results of, the treatment of the disease may be *directly ascribed. But there is another illogical conserva*tism in addition to that above mentioned which is undeniably more serious in this connexion. I allude to the far prevailing belief that only strong solutions of silver nitrate are of any use in the prevention and treatment of purulent conjunctivitis due to gonococcal infection in the adult and in infancy. A recent committee upon this subject in its final report has laid stress upon the use of a 1 per cent. solution of the drug. On paper this may appear to be a solution of very moderate strength. But in actual fact it consists of five grains of the silver nitrate in solution, whereas, for 25 years at least I have found that the strongest solution which is necessary is one which contains no more than one grain of the drug to the ounce of water. A great point has been made of the fact that the mothers of Liverpool, possessing babies at the breast, suffering from gonococcal infection of the conjunctiva, can be admitted, with their infected offspring, into a hospital where the conjunctival inflammation can be at once dealt with by skilled treatment. If this step is necessary for the mothers of Liverpool I can only say it is perfectly unnecessary for the mothers of the district of West London, who come with their babies to the West London Hospital. The mothers of the West London district, or those representing them, cure the babies themselves by the instructions given them, which include the treatment which I have prescribed for 25 years, and a solution of silver nitrate of the strength of one grain to the ounce of water. There is no fuss, no difficulty; the cases are brought twice a week for my inspection, and if the corneæ are intact at the time of the first visit, nothing else happens than perfect recovery from the conjunctival inflammation, no matter of what virulence the infection might be. I have so repeatedly published and taught the lines of treatment by which these results can be attained that it is unnecessary here to allude to them particularly. Meanwhile I am glad to see that my suggestion, *published in a letter to* THE LANCET *at the beginning of the* year, that the International Ophthalmological Congress should appoint a sub-committee to consider the standardisation of the treatment of purulent conjunctivitis in infancy, has been adopted. I am, Sir, yours faithfully,

Wimpole-street, W., June 24th, 1909. PERCY DUNN.

THE USE OF ANTI-DIPHTHERITIC SERUM IN NON-DIPHTHERITIC INFECTIONS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 15th you were good enough to comment editorially (p. 1407) upon a communication (p. 1385) in which I suggested the use of anti-diphtheritic serum in the laryngitis of measles as a matter of routine and without waiting for a bacteriological diagnosis. My point was that the laryngitis occasionally supervening in measles may be diphtheritic in nature, and that therefore such an eventuality should be forestalled by the immediate use of serum. I adhere to that thesis, and as the matter is of some importance in daily practice, may I answer the argument in your editorial note? You maintain that laryngitis is a symptom rather than a complication of measles and only endorsed my plea when that laryngitis was membranous in character. I will only quote one authority to decide between us—namely, Dr. E. W. Goodall in his article on "Measles" in the last edition of Hutchison and Collier's "Index of Treatment" (p. 525). He "strongly recommends that in all cases of laryngitis in *measles occurring in localities where diphtheria is at all* prevalent [and where, may I ask, is it not?], a subcutaneous injection of 4000 units of antitoxin be given." The really important question upon which my critic did not touch seems to me to be whether antitoxin is harmless should the case prove one of other than diphtheritic infection. It is years now that serum has been recommended in conditions very different from the disease for which it was first intended. Thus, it has been used in cerebro-spinal meningitis, in anæmia as a stimulant and tonic, in tetanus, in menorrhagia, and in hæmophilia. Recently in your columns[1] Mr. Frank Argles refers to its value in "cases of quinsy or bad scarlet fever throats."

Now, Sir, my only reason for recommending the serum was on the chance of the infection proving diphtheritic, and the belief that the risk of delay was greater than the risk of an unnecessary injection of antitoxin would alone, in my opinion, justify its use. I do not believe the indiscriminate use of antitoxin to be free from danger, and cannot give entire credence to those *statisticians who compile hundreds* of thousands of cases with no untoward consequences other than slight discomfort, slight urticaria, and slight arthritis. I have myself seen an injection of fresh antitoxin followed, in an adult, in less than 20 minutes, by intense dyspnœa, collapse, and complete unconsciousness, with, as the pulse returned, the expectoration of an enormous quantity of blood-stained froth, and later, by severe arthritis and urticaria. The initial syncopal state lasted not less than two hours, throughout which period death appeared imminent.

In the *Therapeutic Gazette* of March 15th, 1909, Gillette of New York collects 16 cases of death and 10 cases of grave collapse *following injections of antitoxin, in most of* which some respiratory abnormality—asthma, bronchitis, hay fever —had pre-existed. Fatal cases of injections of horse-serum have also been recorded. Of Gillette's fatal cases only two lived longer than ten minutes after the injection. In only one could anaphylaxy be alleged, an injection having been given ten years before. It is impossible to exaggerate the importance of these facts, and I venture, Sir, to conclude that their interpretation should lead us *to extreme care in the use* of antitoxin and to limit its employment to cases in which the diphtheritic poison is evident or suspected.

I am, Sir, yours faithfully,

A. A. WARDEN,

Visiting Physician, Hertford British Hospital, Paris.

June 26th, 1909.

[1] THE LANCET, June 5th, p. 1636.

MEDICAL INSPECTION OF SCHOOLS IN SCOTLAND: THE POSITION OF FEMALE ASSISTANT INSPECTORS.

To the Editor of THE LANCET.

SIR,—As several Scottish councils are at present seeking assistant medical inspectors and offering lower terms for women than for men, I ask your permission to draw special attention to the fact. Edinburgh City, Fife, and Forfarshire, which have all accepted the recognised minimum of £250 per annum for male assistants, offer £200 and £150 respectively for the corresponding female appointments. Several reasons, the ingenuousness of which is doubtful, have been publicly given, such as that the work of the female inspector is to be less important, or that if the female medical inspectors are remunerated at the same scale as males the female teachers will demand like treatment. The fact is that the councillors believe the supply of women to be cheaper than that of men. From the point of view of the profession the services performed by the men and women are equally incumbent on the councils, and as the prospect of advancement before the assistant is even less for women than for men it is desirable that every woman should loyally support the contention that for women as for men a whole time appointment in a service which is almost a drawback for any other department of medical work requires a minimum salary of £250, and that the councils should be made to realise this by receiving no applications for the female assistant inspectorship until the terms are adequate.—I am, Sir, yours faithfully,

Dundee, June 30th, 1909. R. COCHRANE BUIST, M.D. Edin.

A SYSTEM OF DIET AND DIETETICS.

To the Editor of THE LANCET.

SIR,—In your interesting review of the above work in THE LANCET of to-day I am somewhat surprised to find that you had no adverse criticism to offer regarding Dr. Edmund Cautley's account of the Salisbury diet, which, despite the editor's assurance that the book is written "by men who have had special experience of the subjects on which they write," can only be described as incomplete and erroneous. The vital error in Dr. Cautley's article has reference to quantity. Dr. Cautley says that the diet consists of two to four pounds of meat daily and three to five pints of hot water. Does Dr. Cautley mean that certain types of cases are allowed two pounds a day, others four pounds, while others again have intermediate quantities? Or does he mean that all types of cases are placed indiscriminately upon a minimum of two pounds and that this amount is gradually increased to four pounds? Whichever way it may be, a minimum of two pounds a day, divided between three meals (Dr. Cautley does not mention the number of meals), *means nearly 11 ounces at each meal.* As an initial quantity this will in the majority of cases greatly overtax the digestive capacity of the patient and cause disaster. The largest quantity prescribed by Salisbury at the commencement of treatment was eight ounces a meal, and often it was much less. Thus, in chronic rheumatism he commenced with a minimum of two ounces a meal and stopped at a maximum of eight ounces. I am aware that in certain cases—obesity, for example—he gradually increased the diet to a relatively large amount, but only after assuring himself by analyses of the urine and fæces that the patient could take it with advantage. Personally, in cases in which I have prescribed the diet I have found that three to four ounces is usually the most suitable quantity to begin with, and that it is seldom necessary or advisable to increase it beyond eight to ten ounces. I think I am right in saying that this represents the experience of the majority of physicians who have had occasion to prescribe the treatment. Some cases do much better on beef-mince (which Dr. Cautley does not mention) than on beef patties, his recipe for which, by the way, is not the one described in Salisbury's latest work.

I hold no brief for the Salisbury diet, which, in common with all restricted systems of diet, is liable to abuse and should only be prescribed with caution. On the other hand, when limited to carefully selected cases, and suitably modified both with regard to the disease and the individual, it will frequently prove a valuable therapeutic weapon where less drastic measures have failed. Therefore it is to be regretted, inasmuch as Dr. Cautley has written what will undoubtedly be regarded as an authoritative article on the subject, that he has not given a more correct and detailed account of its *rationale*.

I am, Sir, yours faithfully,

Wimpole-street, W., June 26th, 1909. ERNEST YOUNG.

THE DETERMINATION OF SEX.

To the Editor of THE LANCET.

SIR,—In the review published on May 22nd of my book on the "Causation of Sex" you advocate the "accumulation of data of proved scientific accuracy." Towards this collection of data I send you this fact. The birth of a princess to the Queen of Spain on Tuesday, June 22nd, not only entirely confirms my theory, but was correctly foretold by means of the data given on pp. 182, 183 of my book. As the Queen of Spain was delivered on May 10th, 1907, of a boy and expected to be delivered again in June, 1908, it was clear by my theory that her second child would be of the same sex as the first, and so on June 23rd, 1908, the boy Prince Jaime was born; becoming again pregnant and again expecting in June, 1909, it was evident the child would be of the opposite sex to the last, and so a princess was duly born on June 22nd, 1909. So that, as was the case with the Empress of Russia's children, my theory is fully confirmed.

I am, Sir, yours faithfully,

Broadstairs, June 26th, 1909. E. RUMLEY DAWSON.

THE DIAGNOSIS IN PARALYSIS OF THE EXTRINSIC MUSCLES OF THE EYE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of June 19th I read with much appreciation Mr. Angus Macnab's interesting and clever paper on "A Simple Method of Diagnosis in Paralysis of the Extrinsic Muscles of the Eye." I quite agree with him when he says ordinary methods require "a very efficient memory or a severe mental effort." A few years ago I read an article by Mr. Priestley Smith of Birmingham, in which he laid down the following rules for the diagnosis of paralysis of ocular muscles:—1. Ascertain in which direction the images lie farthest apart: the inefficient muscle is one of those which normally turns the eyes in that direction. 2. Ascertain which image belongs to which eye: the inefficient muscle belongs to the eye whose image lies farthest in the said direction. I have carried these rules in my memory and found them of great assistance. I thought they might interest Mr. Macnab.

I am, Sir, yours faithfully,

G. VICTOR MILLER, M.D. Edin.,

Ophthalmic Surgeon, Stockton and Middlesbrough Hospitals.

June 30th, 1909.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University.

THE Bill to dissolve University College, Bristol, and to transfer all the property and liabilities of that College to the University of Bristol, came before the Committee on Unopposed Bills in the House of Commons last week. After some slight discussion the Bill passed and was ordered for third reading. On Thursday, June 24th, the new buildings of the Merchant Venturers' Technical College, which have arisen on the site of those consumed by fire a year or so back, were dedicated by the Bishop of Bristol and formally opened by Lord Reay; and on Friday evening a conversazione was held within the new buildings themselves. They form a handsome and imposing block and occupy a central situation. They are, unfortunately, separated by nearly half a mile from the main block of the buildings of the University, with which the College is now incorporated. The Faculty of Engineering in the University of Bristol will be greatly strengthened by this addition both in teaching staff and in premises. One of the difficulties which the University has to face is the distance of several of its centres of work from the main buildings; the General Hospital and the Royal Infirmary are some minutes' walk from the medical school. This is not, however, so great a drawback as it might seem, for by a judicious arrangement of the curriculum it can be overcome.

The Anatomical Society of Great Britain and Ireland.

This society held its annual meeting in Bristol for the first time on June 25th and 26th. Scientific proceedings were limited to the morning and afternoon of the first day, and were held in the anatomical theatre of the University. On Friday afternoon there was a reception at the house of Mr. P. J. Worsley in Clifton, and in the evening the society and its guests dined at the Queen's Hotel. Professor A. M. Paterson of Liverpool was in the chair, and among those present was Professor Ramström of Upsala. Several of the speakers made apt and graceful allusion to the new University; and all who knew the history of the later stages of its development were glad to find in these speeches some recognition of the untiring efforts of Dr. E. Fawcett, the professor of anatomy and dean of the Faculty of Medicine.

The Recent Epidemic of Scarlet Fever at Sidmouth.

Dr. R. J. Reece, Local Government Board inspector, has issued his report on the inquiry which he recently held in reference to an outbreak of scarlet fever at Sidmouth (Devon) and the sanitary administration of the urban district. Dr. Reece states that from October, 1908, to February, 1909, 52 cases of scarlet fever were notified in Sidmouth; none of the cases proved fatal, and the epidemic was mild and of comparatively small dimensions. Dr. Reece states that the dwellings of the poor are for the most part clean, but in certain localities cottages are crowded together, without any means of thorough ventilation, and adds that there is no systematic inspection of meat and foodstuffs. Dr. Reece says that the town council of Exeter has agreed, since 1905, to receive infectious cases from Sidmouth in its isolation hospital. Dr. Reece suggests that Sidmouth and five adjoining sanitary districts should unite in building an isolation hospital, and in appointing a medical officer who should give his whole time to public health work.

The Local Government Board and the Axminster (Devon) Rural District Council.

At a meeting of the Axminster rural district council, held on June 25th, it was stated that the Local Government Board had written saying that it would sanction the appointment of the medical officer of health (Mr. W. Langran) for another year, but acting upon the advice of Dr. R. Deane Sweeting, who had recently inspected the district, the Board recommended the district council to combine with neighbouring authorities with a view to the appointment of a joint medical officer of health, possessed of special qualifications in public health, who would devote his whole time to public work.

Health of Cornwall in 1908.

The annual report of the sanitary committee of the Cornwall county council for 1908, which has just been issued, shows that the birth-rate during the year was at the rate of 22·44 per 1000, compared with an average of 21·97 for the last five years. The death-rate was 14·75, against 15·08 in 1907. Of the 4763 deaths, 748 were of children under one year, against 678 in the previous year. 187 deaths occurred from zymotic diseases; 133 of these were due to measles, whooping-cough, and diarrhœa. 440 deaths were due to "consumption." The report shows an increased birth-rate, a decreased general death-rate, a decreased zymotic death-rate, a decreased infectious diseases rate, a decreased phthisical death rate, and a decreased percentage of the combined diseases of consumption, bronchitis, pneumonia, and pleurisy.

The Royal Gloucester Infirmary.

The King visited the Royal Agricultural Show at Gloucester on June 23rd, and in his reply to the civic address said: "I am happy to take this opportunity to inform you that I give my permission for the title Royal to be prefixed henceforward to the name of the Gloucester General Infirmary in recognition of the admirable work done by those responsible for its management, and the continued and successful efforts of its staff in the prevention and alleviation of human suffering."

Testimonial to Mr. E. M. Grace.

The Testimonial Fund to Mr. E. M. Grace has now reached about £530.

The Remuneration of Public Vaccinators.

At a meeting of the South Molton (Devon) board of guardians held last week Mr. A. H. Brown tendered his resignation as public vaccinator for the Witheridge District, stating that it was quite impossible for him to carry out the duties for the small fees he received. The guardians decided to ask Mr. Brown to accept a fee of 5*s.* per case, this being the old fee before the recent reduction was made.

The British Dental Association.

The annual meeting of the Western branch of the British Dental Association will be held at the University of Bristol on July 16th.

June 29th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE summer term is practically at an end. The examinations are either completed or are in their final stages, and the departments of chemistry and physics are preparing to move to their new quarters at Bournbrook. The entries for the examinations show a very definite increase, most marked in the departments of the Faculty of Science and in the Faculty of Commerce, whilst the other faculties practically retain the good positions they previously held.

The Hospital Saturday Fund.

Saturday, June 19th, was Hospital Saturday in Birmingham, and the thirty-seventh annual collection made on that day reached the sum of £13,739 0*s.* 3*d.*, or about £1121 less than the amount collected on the corresponding day last year. The Fund will not close for several days yet, and in spite of the bad times, it is still hoped that even if the record sum of £20,632 9*s.* 10*d.* collected last year is not attained this year, the final total will still be over £20,000. On Friday, June 25th, the total amount had risen to £17,554 11*s.* 9*d.*, which is rather more than £1200 less than the total on the same day last year, and if the hope of £20,000 is to be realised the contributions still to come in will have to be larger or more numerous than has usually been the case during the later days of the collection.

The Feeble-Minded.

The truth about the feeble-minded is gradually being put in plain words before the public, and at a recent meeting of the Birmingham education committee Mrs. Pinsent, who has taken so active a part in work associated with the care and control of defectives, spoke very forcibly regarding the necessity for legislation giving legal control over those unable to take care of themselves. In moving the adoption of the report of the special schools after-care committee, Mrs. Pinsent stated that whilst the children improved very much while they remained in school it was found that when they were turned out into the world only 5 per cent. proved capable of earning 10*s.* a week, and many who as soon as they left school became wage-earners fell back into the class of unemployed. The experience of the after-care committee has led Mrs. Pinsent to the conclusion that the mentally defective are persons who require life-long control, some to a greater and some to a less extent, but such control must be provided unless the work spent on them during their earlier years is to be entirely wasted.

Treatment Associated with Medical Inspection.

Worcestershire has initiated a scheme for the purpose of dealing with the cases of children who have been shown by medical inspection to be in need of care and treatment. The draft scheme has been adopted as a basis and a committee has been appointed to draw up a plan based on the scheme and to present it at a subsequent meeting. The scheme suggests a central committee consisting of members of the education committee and sanitary sub-committee, such comup the cases noted by the medical inspectors, to induce the parents to carry out the suggestions of the medical officers, and to persuade parents to enter their children as members of provident dispensaries or friendly societies. It is further suggested that the local committees should endeavour to provide the necessary help in special cases, and in cases of criminal neglect should report to the education committee. The scheme seems practicable and workable, and the plan will be awaited with interest. The position of the medical officer to the clubs must be protected if children are to be sent to some of these institutions for treatment.

The South Staffordshire Small-pox Hospital.

At a recent meeting of the South Staffordshire Small-pox Hospital board a suggestion for the utilisation of the hospital for the treatment of phthisis from an educational point of view was considered. The scheme emanated from Dr. George Reid, the medical officer of health for Staffordshire, and its central idea is that phthisical patients should be sent to the hospital for a limited time, not especially for treatment but to be taught how they should live at home. The scheme would necessitate the erection of some shelters, a medical officer, a small number of nurses, and a domestic staff. Dr. Reid believes that it would be safe to use the buildings for the purpose he desires provided certain parts are left vacant for the reception of any small-pox cases which may arise, and he thinks the cost in upkeep of 35 beds would not exceed £2767, whilst at present the upkeep is costing £1530, for which nothing is being obtained.

Town Funds and Hospital Necessities.

The financial difficulties of the Walsall and District Hospital led the committee of the hospital to apply to the general purposes committee of the town council for an annual grant towards the upkeep of the hospital. The general purposes committee reported that it was unable to accede to the request, and on the report being presented it was proposed by a member of the council that the trading committees of the corporation should be empowered to subscribe to any of the charitable institutions of the town from which their employees received benefit. The suggestion obtained support, but it was pointed out that the eventual result would be to place the hospital on the rates, and on a vote being taken the motion was defeated by a large majority.

June 29th.

MANCHESTER.

(From our own Correspondent.)

Treatment of Consumptive Poor.

At a meeting of the Salford guardians held on June 25th it was decided to confirm the action of the general purposes committee in approving the majority of the recommendations issued by a committee appointed by the North-Western Poor-law Conference in regard to special treatment of phthisical cases. For the treatment of out-door poor coöperation was urged between health authorities and guardians, separate sleeping accommodation for consumptives, the distribution of helpful literature by relieving officers, and the sending of special nurses periodically to consumptive poor people. For the indoor poor, isolation and special treatment, especially as to open air, were urged. It was also agreed to hold a special meeting of the general purposes committee to discuss the need for more suitable accommodation for the housing and treatment of consumptives at the Hope Hospital, and to consider the advisability of utilising some land adjoining the hospital which belongs to the guardians.

Margarine and Butter.

The question of margarine *v.* butter, or of butter-cum-margarine, is one of considerable interest for a large section of the population of Manchester, so that the proceedings of Standing Committee B of the House of Commons on June 21st may fairly be noticed in a communication from a city which will be so largely affected as Manchester in the "Sale of Margarine Bill" introduced by Mr. Kilbride. The object of the Bill is to prevent margarine from being so coloured as to resemble butter, and so to prevent its fraudulent sale as such. The opposition to the Bill on the part of certain of the Members for Manchester was curious, and their reasoning, so far as reported, not easy to follow. Mr. Byles, one of the Members for Salford, moved to delete Clause 1, the operative clause of the Bill. He said that "the fact that margarine was coloured to resemble butter did not mean that it was fraudulently sold as butter. Imitation was the sincerest form of flattery. Ladies who could not afford a silk dress sometimes wore mercerised cotton, and he did not think they should be prevented from buying such an imitation. There was the artificial flower trade. People were sometimes deceived in that way. A little while ago he bought on the kerbstone a penny bunch of violets. When he got it he found that it was made of paper. He did not suggest, however, that Parliament should interfere." Such reasoning as this would justify any amount of adulteration. If the resemblance of margarine to butter were made close enough it would at any rate make fraud easy and make it tempting. The illustration given by Mr. Byles does not apply, and is therefore irrelevant. Ladies do not buy mercerised cotton thinking it silk. Mr. Harwood said that the people guilty of fraud were not the makers of margarine but those who bought it and mixed it with butter. Mr. A. H. Scott opposed the Bill because he said "it proposed to injure 90 per cent. of honest traders for the sake of getting at a small proportion of dishonest people," and he told the story of two clever young Irishmen in Manchester, who have been heard of before, who bought margarine to sell it to retailers, and they in turn bought it to sell to the public as butter. They sold 20 pounds or 30 pounds a week to each retailer, and undertook themselves to pay any penalties that might be imposed on the retailers if they were found out. It was easy to convict the retailers, but so far it has been impossible to catch the two clever Irishmen. Sir F. Cawley opposed the Bill as he said his constituents would have to pay more for their butter if it were passed. Some of our legislators do not take a very stern view of adulteration, but it is satisfactory that the penal clause was passed by 23 votes to 13. If margarine is sold on its merits all well and good, but if it is sold as butter the fraud should be punished.

Town Planning Bill.

A petition in favour of the Town Planning Bill has been forwarded to the House of Commons by the Manchester and Salford Sanitary Association and will be presented by Mr. Joynson-Hicks, M.P.

Should Hospital Patients Smoke?

One of the medical officers of the Hope Hospital has recommended to the committee of the Salford guardians that if the luxury of smoking be allowed it should take place only out of doors. This rather hard measure has not been meted out to the inmates, chiefly through the sympathetic pleading of one of the lady guardians. She pointed out that it would be a great hardship on the paralytics and bed-ridden, and it was finally determined that regulations should be drawn up permitting bed-ridden patients to smoke at certain hours and giving reasonable latitude to those desirous of smoking in the day rooms.

Langho Reformatory.

Regrets have often been expressed that the results of detention at the Langho Reformatory for Inebriates have in so many cases been apparently *nil*, but an effort is being made to do something more than keep these poor women there for a time, and then dismiss them without any attempt to help them to resist their special temptation. The Chief Constable of Manchester, Mr. A. Peacock, has written to the board of management suggesting that it might be possible to get together a number of ladies to take an interest in women patients after their period of detention had expired. Through them the women might be kept straight and honest work might be found for them. It is said that the board favours the idea, and it is earnestly to be hoped that it will be carried out. A tactful, strong, but sympathetic influence is just what is required in many of these cases to prevent the victim of drink from falling back into the old ways.

June 29th.

SCOTLAND.

(From our own Correspondents.)

Death of Professor D. J. Cunningham.

As was recently noted in The Lancet, the state of health of Professor Cunningham, who occupied the chair of anatomy in the University of Edinburgh, was giving his friends the gravest anxiety. He had sojourned in Egypt during the winter without material benefit, and when he returned to Edinburgh it soon became known that only one issue of his illness was to be looked for. He died on June 23rd, and was buried on the 26th in the Dean cemetery. The funeral service was conducted in St. Cuthbert's Church. The principal part of the service was taken by the Rev. Professor Taylor, the prayers being highly impressive [illegible] to the occasion. The members of the University [illegible] the Senatus, were present in [illegible] of the Royal Colleges of Physicians and of Surgeons were present in academic costume and attended by their mace-bearers. The students were present in large numbers and many public bodies were represented. In the whole Edinburgh School of Medicine Professor Cunningham's death is not only deeply mourned on account of his personal attractiveness, but it is felt that the medical faculty of the University has sustained an almost irreparable loss.

Death of Two Edinburgh Medical Men.

At Boscombe, Bournemouth, on June 25th, there passed away in the person of Peter Alexander Young, M.D. Edin., F.R.C.P. Edin., one who was well known in Edinburgh medical circles for many years. Dr. Young graduated in medicine at Edinburgh in 1867. He practised in Portobello for many years, but over 20 years ago removed to Edinburgh, where he had a large general and family practice. For many years he was honorary treasurer to the Royal College of Physicians, and in that capacity had frequently to represent the College on public occasions, a duty which he always performed with dignity and acceptance and to the satisfaction of the Fellows. He was a keen Volunteer and took an active part in ambulance work. He was a justice of the peace for the County of the City of Edinburgh. He took an active part in various philanthropic movements. His genial and friendly bearing made him a favourite with his brethren, and his patients were much attached to him. Failing health compelled him to resign his connexion with his College, and soon thereafter led him to abandon practice and to seek the milder climate of Boscombe, where his death took place.—On June 24th, at Newton, Nairn, William Alexander Finlay, M.D. Edin., F.R.C.S. Edin., recently of Trinity, near Edinburgh, passed away. Dr. Finlay came of a medical family and succeeded his father in general practice in Trinity. Until his health began to fail he was the leading practitioner in the district and was well known to his brethren in Edinburgh as an excellent practitioner. Some years ago he was one of the surgeons to Leith Hospital. He died at the house of his brother, Sir Robert Finlay, himself at one time a student of medicine and Attorney-General in the last Unionist Government.

The Responsibility for the Treatment of Consumptives in Glasgow.

The parish council of Glasgow has felt for some time that too much of the responsibility for the treatment of consumptives rests on its shoulders. It does not fall within the powers of the council to undertake the treatment of the consumptive at the period of his illness most likely to result in recovery—i.e., when he is still able to work; but at a later period, when the disease is so advanced as to render him unfit for work and correspondingly more unlikely to recover, he is sent to one of the parish hospitals for treatment, and his wife and family are thrown upon the rates for support. As the council has not the power to interfere at the earlier stage of the disease, while the man is still a possible wage earner, it has for some time been urging upon the corporation that it is its duty to undertake the responsibility of these cases in the earlier stages. It is impossible to deny that such a course is economically as well as medically sound, and in order to consider the whole matter the corporation's sub-committee on the prevention of tuberculosis has had a meeting with representatives of the parish councils of Glasgow and Govan, the National Association for the Prevention of Consumption, Quarrier's Homes, and the Lanfine and Bellefield sanatoriums. As a result of this meeting a memorandum has been prepared by Dr. A. K. Chalmers, medical officer of health of Glasgow, suggesting the following points for consideration: (1) That phthisis be included among the notifiable diseases for a period of three or five years; (2) that in addition to the tuberculosis dispensary, at present conducted in the sanitary chambers, similar facilities be provided in the eastern, western, and southern districts of the city; (3) that a nurse be appointed to each dispensary for systematic visitation of the houses and families of those in attendance thereat; (4) that the work of home visitation be placed under the charge of a medical assistant appointed for the purpose; (5) that until additional hospital accommodation is available for infectious diseases the parish councils of Glasgow and Govan be invited to consider the conditions under which cases of the class formerly admitted to Baird-street Reception House may be accepted by them; and (6) that the local branch of the National Association for the Prevention of Consumption and the friendly societies be invited to a conference to consider the question of making further provisions for assisting the consumptive worker to obtain the benefits of sanatorium treatment.

Abuse of Medical Charities.

At a recent meeting of the Glasgow and West of Scotland branch of the British Medical Association the branch council reported on its inquiry into the alleged abuse of medical charities. It stated that circulars were issued to members of the medical profession in Glasgow and the neighbourhood asking for specific instances of the abuse of medical charities. The Council received only 49 replies to 600 circulars. In face of so limited a response it thinks that it can hardly be asserted that the medical profession in Glasgow suffers to any large extent from the abuse of medical charities. It appears, however, that there is a certain amount of abuse, and unfortunately it is frequently associated with cases recommended by medical men. The general view appeared to be that such abuse as exists is confined mainly to outdoor departments and dispensaries.

Medical Tutors for the University of Glasgow.

Under the will of Dr. John Hall, a graduate of the University of Glasgow, who died last April, the University will ultimately benefit to the extent of about £40,000. This sum has been left to the Senate of the University of Glasgow as an endowment for the foundation of tutorial fellowships in connexion with the study of medicine, surgery, and midwifery at that University, to be called the "Hall Tutorial Fellowships,"

fessors of surgery, medicine, and midwifery. The fellowships are to be awarded after examination (either special or part of the graduation examination) and each of the fellowships is to be of the value of £200 per annum, payable in advance at the beginning of each session. The fellowships, of which there are to be as many as the income will permit, are to be held for three years, and may not be held with any other scholarship, bursary, or other educational emolument. Also the Fellows are to live within three statute miles of the University and are to devote their whole time to practical instruction of students under the direction of the professors, and may not engage in any private practice or tuition.

The Remuneration of Medical Officers of Schools.

A meeting was held in the Medical Club, 22, Carlton-place, Glasgow, on June 29th, of representatives from all the medical societies of Glasgow to consider the question of medical inspection of school children, and more especially the remuneration that it was proposed to give to the medical officers about to be appointed. A number of gentlemen spoke, and while several were of the opinion that no part-time appointments should be made, on the motion of Dr. W. A. Caskie it was unanimously resolved that the remuneration to the quarter-time medical officers, whom the School Board propose to appoint, be made on the basis of a sum of half a guinea per hour. It was further unanimously agreed that a small committee be appointed to draw up a memorial embodying the views of the meeting as expressed by Dr. Caskie, and that this same committee be empowered to go as a deputation to the School Board should they consider it advisable.

Surgical Operation in the Street.

At Dumbarton recently a most unfortunate accident occurred to a boy through standing on the step of a friend's bicycle. The boy was barefooted, and his right foot became entangled with the chain and gear-wheel and was severely crushed. Although medical assistance was at hand the foot could not be released without amputating the great toe, and this operation was carried out on the pavement, after which the boy was removed to the cottage hospital.

Treatment of the Insane in the Rathven Colony.

Attention is called in the report of the General Board of Commissioners for Lunacy for Scotland to the success which has attended the efforts of the parish of Rathven to provide for its patients under private care. 50 per cent. of the insane chargeable to it are thus provided for. In the present year the total chargeable insane of the parish is 56, an increase in 14 years of no less than 126 per cent., of whom 28, or 50 per cent., were met with in private dwellings. The colony, numbering 44 patients (26 males and 18 females), is scattered over a district six miles by five situated in the parish of Rathven. The patients are lodged with crofters and small farmers. Of the ailments 27 were imbecile, 9 demented, 4 maniacal or melancholic, delusional insanity accounted for 1, while there were three ill-defined types. The ages were from 15 to 80. Six were paid for at the rate of 3*s.* per week and under, five at a rate exceeding 3*s.* and under 5*s.*, 24 exceeded 5*s.* and under 6*s.*, and ten from 6*s.* to 7*s.* As regards the productive capacity of the patients, 7 per cent. are classed as very good, 24 per cent. as good, 21 per cent. as moderate, and 48 per cent. as useless. The movement to develop and to extend the family care of the insane, at first looked at somewhat askance, has been approved, encouraged, and developed to the extent indicated chiefly owing to the enlightened management of the colony.

Forfarshire School Boards and the Medical Inspection of School Children.

A conference of the Forfarshire school boards with the Forfarshire secondary education committee was held on June 23rd to consider the question of the medical inspection of school children. It was agreed to appoint Dr. N. J. Sinclair, medical officer of health of the county, chief medical officer at a salary of £200. He will be expected to devote about half his time to the work of supervising the medical inspection of the children. It was also decided to give Dr. Sinclair a male and a female assistant, whose whole time will be given to the examination and supervision of the children. It was agreed that the first male assistant should be appointed at a salary not exceeding £250 and that the second assistant female should be appointed at a salary not exceeding £150. It was also agreed that the sum of £150 per annum should be assigned for travelling expenses for the school medical officer and his assistants, and that the sum of £120 should be assigned for the payment of the salary of a clerk-typist and for the expenses of stationery and printing. It was also decided to provide each school in the county with a weighing machine and a measuring rod.

Outbreak of Typhus Fever in Dundee.

An outbreak of typhus fever has been reported by Dr. C. Templeman, medical officer, Dundee. There have been nine cases, and the infection is believed to have been traced to the selling of the effects of a person who had died from it. Comment was made in the meeting of the public health committee as to the sales of old clothes, &c., on ground let by the town council for the purpose, and on the dangers of infection therefrom, and the question was raised as to whether the sanitary authorities had not power to put a stop to it. The outbreak has so far been confined to two families.

Death of Dr. William Hunter of Hong-Kong.

The death of Dr. William Hunter, Government bacteriologist, Hong-Kong, has been announced by a cablegram dated June 10th. It must be feared, since his professional duties called upon him to visit natives suffering from plague and other infectious diseases, that his death was due to infection in some form. Dr. Hunter was the son of the late Rev. William Hunter, Macduff parish church, and had a successful career at the University of Aberdeen. In 1896 he won the John Murray medal and scholarship, and in 1897 the George Thompson Fellowship, graduating the same year with honourable distinction. He is survived by his wife and one child. While he and his family were home on holiday last year in London, the other of his children met death by falling down a lift.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Municipal Improvements: Extension of Main Drainage System.

AN inquiry of great importance to the Dublin ratepayers was carried out last week in the city hall before the chief engineering inspector of the Local Government Board. It dealt with the application of the corporation for sanction of the following loans: £100,705 for extending the electric lighting mains and plant; £100,000 for completing the main drainage; £17,400 for erecting lodging-houses for the working classes at Inchicore; £10,632 for completion of refuse destructor; £10,000 as advances under the Small Dwellings Act; £10,000 for carrying out street improvement works; £1320 for the lighting of Drumcondra and the North Circular-road by electricity; £1006 for private improvement expenses; and £2365 for carrying out street improvement works at the Ranch, Drumcondra. Regarding the provision for completion of the main drainage, evidence was given of the particulars of the population of each of the new districts which it was proposed to connect with the main drainage scheme; also of the quantities of sewage which would be carried in the new mains. It was estimated that the total accession of sewage would be to the amount of 3,697,200 gallons. The population already connected was 215,065, and the number which it was now proposed to connect was 88,424. When the drainage was completed the total flow would be 15,187,200 gallons per day. The inspector asked whether the additional connexion would have the effect of making the Liffey brighter and purer than it is at present. The reply was an unhesitating affirmative, which will be confirmed by all who remember the June odours of the Liffey a few years ago, and the improvement which has already arisen from the drainage works.

Death of a Crimean Sister of Charity.

By the death of Sister Theresa, Reverend Mother of the Sisters of Charity in charge of the nursing of the Cork North Infirmary, a notable personality has passed away. During the Crimean war, when she was quite a young nun, she volunteered to go to the front to nurse the sick, the wounded, and the dying. She partook of the great privations of the troops, and her bullet-pierced garments, affectionately preserved by the members of her order, are a proof that in the cause of mercy and charity she did not hesitate to advance into the fighting-line. About 12 years after her return from the Crimea she was appointed Sister Superintendent at the Cork North Infirmary and brought to the discharge of her duties a clear intelligence combined with a most kindly disposition. Many past students of the hospital will hear of her death with regret.

Fever Cases in Londonderry.

At a meeting of the Londonderry board of guardians held recently a report was adopted, by 16 to 15 votes, with reference to the proposed amalgamation of the City Fever Hospital at Foyle Hill and the Union Fever Hospital. The guardians offer to pay £75 per patient annually out of the Union funds on condition that the corporation take over their entire liability in respect of hospital accommodation for fever and other infectious diseases, and that the corporation provide for and maintain all poor persons suffering from such diseases for the treatment of which the guardians are at present responsible; and, further, that any fever patients residing in the rural districts who are able to pay for treatment and wish to go into the Foyle Hill Hospital shall be admitted and charged no more than the scale of charges which applied to the city patients. The corporation is asked also to provide for all improvements and enlargements to be made at Foyle Hill Hospital at a cost of not less than £1500, subject to the approval of the Local Government Board. A committee was appointed to confer with the representatives of the corporation on the matter.

The Prevention of Tuberculosis (Ireland) Act.

At the weekly meeting of the rural council of Omagh held recently, a letter was read from the Local Government Board in the form of a memorandum on the objects of the Tuberculosis (Ireland) Act, 1908, to which was appended a summary of its provisions and also a copy of an order made by the Board prescribing the forms and stages of tuberculosis *to which, and the circumstances in which* Section 1 of the Act applied. The chairman said it would be very unwise for that council to adopt Section 1 of the Act—i.e., the section dealing with notification and disinfection—as its powers were compulsory. He thought that they should do all they could to prevent tuberculosis spreading without resorting to compulsion. Better evidence than such views could not be found in proof of the foresight of those who advocate compulsory powers under the Act, as without these powers it is clear that many county and rural councils will shirk their duty, and as a result nothing will be done to check the disease. Permissive legislation in public health matters is likely to end in failure.

The Queen's University of Belfast.

Sir James Henderson, M.A. Dub., D.L., chairman of the technical and library committee of the Belfast city council, has been appointed by the Crown a member of senate of the Queen's University of Belfast in place of Dr. Peter Redfern, Regius professor of anatomy, who has resigned.

June 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Indirect Massage in Ophthalmic Practice.

AT a recent meeting of the Société de Kinésithérapie M. Wetterwald, speaking on the subject of indirect massage [illegible] the tissues above or on [illegible] organ to be acted on were [illegible] of promoting the formation of a cicatrix or removing congestion. In this way an effect was produced indirectly on the circulation and innervation of the part in question. In the case of a young girl who had suffered for three months from relapsing keratitis with photophobia, lacrymation, and closure of the eyelids, M. Wetterwald found that all these symptoms disappeared in eight sittings. The treatment consisted in kneading (*pétrissage*) the tissues of the cheek, temple, and forehead without touching the eyeball or the eyelids, and this massage of the region supplied by the superior maxillary nerve influenced the special structures of the eye. M. Mesnard, speaking on the subject of the paper, said that the disappearance of congestion caused by the act of mastication was another indirect effect of a similar kind. He had often observed this phenomenon in his own case during attacks of conjunctival congestion.

Hay Fever.

At a meeting of the Academy of Sciences held on June 21st M. Delage submitted on behalf of Dr. Pierre Bonnier a memoir on hay fever, mentioning that the pollen of the gramineæ was for the most part not responsible for the production of attacks, because some patients were affected only at sea or in snowy weather, or under conditions of the most dissimilar kind, or at times of the year when no plants were in the stage of inflorescence. Hay fever was a definite bulbar trouble, a disorder of certain secretory nervous centres with hyperæsthesia of the exposed mucous surfaces and spasmodic reflex expulsive efforts; it was, in fact, a true diathesis and frequently associated with other functional abnormalities, [illegible]eatment ought to aim [illegible] bulb and reducing the [illegible] This could generally be done, he said, by applying the cautery to very small points in certain areas of the nasal mucous membrane—a procedure which had a sedative action. Energetic cauterisation, on the other hand, produced unsatisfactory effects, and must be carefully avoided.

The Antitryptic Power of the Blood Serum as a Means of Diagnosis.

At a meeting of the Academy of Medicine held on June 15th M. Widal communicated a paper by M. Poggenpohl of St. Petersburg, who has investigated the antitryptic power of the blood serum in M. Widal's laboratory and has made observations on 112 patients by the method of M. Marcus. *M. Poggenpohl has found that the antitryptic* power was as a general rule increased in cases of cancer and lobar pneumonia, whilst in other acute and chronic diseases the antitryptic index was almost always normal. The estimation of the antitryptic power of the blood serum, proposed by M. Brieger and M. Frebing for the diagnosis of cancer, was therefore of great importance in symptomatology. M. Poggenpohl did not share M. Brieger's opinion that this reaction was an indication of cachexia, because, on the one hand, he had met with it in many persons without evidence of cachexia, and, on the other hand, he had failed to discover it in many persons presenting a cachectic condition but not suffering from cancer. This property of the blood ought to be regarded as a means of defence and immunisation; antitrypsin seemed, in fact, to be a true antibody elaborated by the organism as a protection against the entrance of a proteolytic ferment which might originate in various ways.

Plague in Tunis.

At a meeting of the Société de Pathologie Exotique held on June 5th M. Conseil said that in the town of Tunis he had examined rats and their ectoparasites in reference to the propagation of plague and had arrived at results in conformity with those obtained by M. Billet in Algeria. When M. Nicolle and M. Sicre were making their investigations at the time of the plague epidemic, it was found that 8 per cent. of the rats that were caught were infected with the bacillus of plague. Although there had been no plague in the human subject since the month of February, M. Conseil had nevertheless found three infected rats. The disease was therefore endemic among those rats, a dangerous condition of things which ought to be combated by destruction of the animals.

Election to the Academy of Medicine.

M. Schwartz, surgeon to the Hôpital Cochin and *professeur agrégé* at the Faculty of Medicine, has just been elected a member of the Academy of Medicine in the section of surgical pathology.

Burglary at a Laboratory.

During the night between June 16th and 17th the laboratory of the Faculty of Medicine of Nancy was entered by burglars, who carried off instruments and apparatus of platinum and silver valued at 4000 francs.

Surgical Treatment of Renal Calculus.

At a meeting of the Surgical Society held on June 9th M. Pousson submitted statistics of 30 consecutive cases of renal calculus on which he had operated, suppuration being present in 20 of them but not in the remaining ten. In one of the ten non-suppurative cases nephrectomy was performed in consequence of an error in diagnosis and was followed by recovery which was maintained for ten years without relapse. Nephrectomy performed in the other nine cases was followed by one death, for which the operation was not responsible, as the patient succumbed to cerebral hæmorrhage 21 days afterwards. With one exception, all the other patients operated on, who could be traced, were alive and in good health. The longest time which had elapsed since the operation was five years and ten months, the shortest time being six months. The 20 cases attended with suppuration comprised three of pyelitis and 17 of pyelonephritis. The three former were treated by nephrectomy and recovered without the formation of fistula, the times elapsed since the operation were respectively five years, four months, and two months. Of the 17 cases of pyelonephritis six were treated by primary nephrectomy, with five recoveries and one death from anuria; six were treated by nephrotomy, with one death under chloroform, two deaths from shock, one death from anuria, and one death at a late stage from septicæmia, the sixth patient being still under treatment. In four cases, all of which terminated in recovery, nephrotomy had to be followed by secondary nephrectomy.

June 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Neuralgia of the Trigeminus Nerve.

AT a recent meeting [illegible] Aerzte Dr. Flesch read a paper on [illegible] of the Trigeminus Nerve. He [illegible] method invented by Dr. Schloesser, in which alcohol was injected into the foramen ovale or the foramen rotundum in the base of the skull where the nerve emerged. This procedure required considerable anatomical knowledge and manipulative dexterity, so that it could not be carried out by the general practitioner. In the modification suggested by Dr. Flesch the alcohol was injected into the peripheral nerve fibres, which was easily done and easily learned. He injected 1 cubic centimetre of alcohol of 80 per cent. strength, and if necessary the dose might be repeated the next day or even on four consecutive days. The result in the 19 cases so treated has been excellent so long as it lasted, but the benefit was unfortunately not permanent, for after about ten months the pains returned, indicating a regeneration of the nerve. The injection might then be repeated, and this could be done as often as relapses occurred. These peripheral injections were not so effective as the central injections into the foramen, but they were much more readily made. Of course, the extirpation of the semilunar ganglion or ganglion of Gasser was the best method, but its disadvantages, such as the complete paralysis of certain masticating muscles and the danger incurred by the eye, were rather serious. Dr. Flesch has observed that cases in which the nerve had previously been resected peripherally were not suited for his method. He has not had any result in cases of disease of the trigeminus nerve, whether of hysterical or traumatic origin. The discussion following this paper was very interesting from the practitioner's point of view. It appeared that there were several other methods which might be useful in this condition. For instance, Dr. Gussenbauer and his school have obtained recovery in such cases by violent purgation, and calomel followed by two or three pints of saline bitters was even now in use in the clinic for such nervous conditions. Ligature of the carotid artery has been tried without satisfactory result. The very drastic method of trephining over the fissure of Rolando on the opposite side, with splitting of the dura mater, has been tried by Jaboulay and Lorenz with variable results. Professor Grossmann reported 17 cases in which he succeeded in completely relieving attacks of tic douloureux by galvano-caustic destruction of the anterior end of the middle turbinal. Dr. Weil said that he had seen benefit produced by galvano-cauterisation of certain areas on the septum of the nose. He therefore believed that many attacks were due to irradiation, originating from minute lesions of the nasal mucosa, and for this reason all other remedies ought to be tried before resorting to the dangerous and not absolutely reliable operation of evulsion of the nerve or removal of the ganglion. Professor Fraenkel said that he had in several instances removed the second branch of the nerve by a novel route from the canine fossa and through the antrum of Highmore with very satisfactory results. This method was safe and not attended with very much hæmorrhage. From the opinions expressed in the discussion it was to be gathered that there was not as yet any one method applicable to all cases of trigeminal neuralgia alike, but that much could be done to relieve the sufferings of the patients.

A New Method of Inhibiting the Action of X Rays and Radium.

Following up a series of experiments on plants, Dr. Gottwald Schwarz has described in a paper read before the Gesellschaft der Aerzte observations made by him with regard to a method of increasing the penetrating power of the X rays without injuring the skin. He said that practitioners using the rays could not help feeling that a more decided effect might be produced on the disease if more rays could be sent into the deeper structures without harm to the superficial layers. He had found that vegetable seeds in their stage of inactivity were unaffected by exposure to X rays on an enormous scale; but as soon as the process of metabolism had begun a very small exposure was sufficient to produce effects of the nature of disturbance. Dr. Schwarz concluded that the degree of the metabolism of a living tissue was very important in regard to its permeability for the rays. He treated an extensive nævus by means of a radium capsule, which in one instance was placed loosely on the nævus, whilst the next time the area adjoining the nævus was covered by the capsule under pressure exerted by means of a tight bandage. In this way the skin was made anæmic and the metabolism was so to say stopped. The difference in reaction was most marked. The area exposed without pressure was after four weeks the seat of intense inflammation with consecutive desquamation and atrophy of the vessels, whereas the area exposed under pressure did not at any time show more than a slight hyperæmia. A similar observation with X rays had a similar result. A boy suffering from trichophytosis was treated by exposure to the rays. One area was covered by a thin plate of wood, another area of equal size was exposed to the same tube at the same time, but it was covered by an equal-sized plate of wood which was pressed firmly against the bone by means of attached weights. After the lapse of 17 days from the exposure the area with pressure exerted on it was just the same as before, but the control area was free from hair. Dr. Schwarz believed that pressure was only one means of lowering or stopping the process of metabolism locally. Freezing could also be used, but more observations were necessary for ascertaining the best methods of procedure.

The Contest between Medical Organisations and the State.

Various medical organisations have lately in several instances caused certain medical appointments to be boycotted, and the corporations thereby affected, which are mostly clubs, have appealed to the law courts against this method of counteracting their machinations. These appeals having elicited judicial decisions unfavourable to the medical profession, the Reichsverband Oesterreichischer Aerzte-Organisationen (Union of Austrian Medical Organisations) has now been induced to take the matter in hand, and has forwarded to the Ministry of Justice a resolution containing explanations as follows: "A boycott has been defined as an appeal to practitioners to refrain from competing for an appointment which has become vacant for one of the three following reasons: (1) dismissal of a medical practitioner from the position in question without sufficient cause being assigned; (2) resignation of a practitioner on the ground of inadequate remuneration, so that the acceptance of the appointment by another man would mean underselling; and (3) differences of opinion between the practitioner and corporation on points of principle or for motives of a social or ethical nature. These three conditions have been consented to by all representative bodies of the profession in Austria and cannot be interfered with by legislation, as a simple appeal from one group of medical men to another group cannot be prohibited." The organisation has taken care to eliminate all coercive measures from its programme as regards the boycott, so that the authorities or magistrates may have no pretext for interference, whilst the sense of common interest is already strong enough amongst the profession to make every practitioner understand the words of Virgil: "Nam tua res agitur." The result has been that in three instances already the union has succeeded in securing for its members adequate remuneration from public bodies, because it was found that other conditions than those insisted on by the union could not induce any regular practitioners to accept the vacancy in spite of the assistance given by the state to the other side.

June 28th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending May 15th show 4578 deaths, compared with 4279 in the week preceding. Bombay Presidency reported 446, Bengal 263, the United Provinces 758, the Punjab 2786, Burma 39, and Rajputana 249. Plague has at last appeared in the Kangra Valley, where 17 cases with 13 deaths occurred during the week ending May 8th.

Lauder Brunton Lancets.

In an official report published by the Lieutenant-Governor of the United Provinces some interesting details are given regarding the use of the Lauder Brunton lancets and permanganate of potash for the cure of snake-bite. The results vary a good deal in character. In Meerut district the lancets were used in 235 cases and success followed in 171 of these, but it is not certain that in all these cases the bites were those of poisonous snakes; in 22 cases the patients died. In Barabanki four cases were successfully treated and in two of them the snakes were seen to be cobras. Other districts report success in several cases, but the returns are not so trustworthy, as it was not always proved that the snakes were venomous. The Commissioner of Agra reports that the villagers are afraid of the lancet and prefer their own methods of treatment, while one magistrate says there *is general complaint that the lancets are not sharp* enough to make proper incisions where the skin is hard.

Malarial Fevers in Bengal.

Malaria has lingered in Bengal far beyond the cold weather, and the Government has now resolved to extend even further the State supply of cheap quinine through various local agencies. The plan adopted in the Punjab is being followed, as good results have been gained in that province.

The Central Research Institute at Kasauli.

Perhaps it is not so widely known as it should be that the Pasteur Institute at Kasauli serves as the provincial laboratory of the Punjab, and as such does a large amount of useful as well as important work. Last year 675 specimens of various kinds were examined, including 457 cases for serum diagnosis for both typhoid and Malta fevers, 69 of examination of blood for malaria parasites, 62 of examination of sputum and other discharges for tubercle bacilli, and 32 of examination of tumours. The total number was less than in previous years, owing to orders having been issued from army headquarters, medical division, that all specimens from military hospitals were to be sent to the brigade or divisional laboratory concerned, and that only those in connexion with rabies were to be forwarded to the Pasteur Institute. It is stated that the majority of the specimens sent to the laboratory in past years had come from military medical officers. The director of the institute hopes that "in course of time the civil surgeons of the Punjab will recognise that a laboratory exists for their own special use."

The Indian Medical Service.

Important despatches have passed between the Viceroy and the Secretary of State regarding the proposed restriction of the Indian Medical Service in order to promote the growth of an independent medical profession in India. The Government of India, in reply to a communication from the Secretary of State, has pointed out the various difficulties in the way of taking the step indicated, but it does not consider the difficulties insuperable and, providing the war reserve of officers of the Indian Medical Service and the attractiveness and efficiency of the service are not interfered with, it is prepared to recommend that candidates from outside should be appointed to posts at present filled by the Indian Medical Service. The Secretary of State expresses satisfaction that the Government of India favours his suggestion. He states that he has "decided that the time has now arrived when no further increase of the civil side of the service can be allowed, and when a strong effort should be made to reduce it by gradually extending the employment of civil medical practitioners recruited in India." In directing the Government of India to consider what appointments can best be filled in this way, Lord Morley lays down the following specific instruction: "When it is found impossible to obtain a man from outside the I.M.S. to fill a particular new civil appointment, or one which has not previously been so filled, I will not object for the present to that service being drawn upon, but the vacancy so caused must be filled from outside it—i.e., no appointment must be made in succession which would involve an addition to the cadre of the I.M.S." The Government of India is asking the opinions of provincial Governments on the subject, and will subsequently make recommendations to the Secretary of State as to the methods by which the proposals shall be carried out.

Indian Medical Service Study Leave.

The regulations regarding the grant of study leave to officers of the Indian Medical Service, as published in the Department of Military Supply, Notification No. 16 of 1907, are reconstructed as follows: Study leave may be taken at any time, but will not be granted more than twice in the course of an officer's service. This restriction does not, however, apply to an officer who has part of his furlough converted into study leave under Rule 8. Officers on furlough, or other leave, who wish to have part of it converted into study leave, should address the Under Secretary of State, India Office, and should attach a statement showing how they propose to spend the study leave. Similarly officers on furlough or other leave who desire to have it extended for the purpose of study should address the Under Secretary of State, but in addition to the statement of the proposed study, they must support their applications with documentary evidence of their having obtained the approval of the authorities concerned in India to their applying for an extension of leave.

May 25th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Opium Smoking.

THE police are very active in endeavouring to detect illicit traffic in opium, and raids on Chinese and on vessels arriving from the East are of daily occurrence. The drug has become so valuable that many Europeans are engaged in the smuggling operations. According to police statements opium is now very scarce in Victoria. A pipeful costs from 1*s.* to 1*s.* 6*d.*, while a 1-pound tin will fetch £4. Most of the old evil dens in the Melbourne slums are now no longer existent.

Sanatorium Treatment.

Dr. Norris, chairman of the Board of Public Health of Victoria, recently stated that at the Greenvale Sanatorium for Consumption (a Government institution near Melbourne) 868 patients had been received from May, 1905, to December, 1908. In about 60 per cent. of these cases the disease was arrested or the patient's condition much bettered, 14 per cent. were discharged as incurable, and at least 30 per cent. fully regained their health. The death-rate from consumption is stated by Dr. Norris to have fallen in this period from 11·76 to 9·58 per 10,000 over the whole State. In Melbourne the fall is from 15·5 to 11·6; in Ballarat from 16·00 to 10·49; and in Bendigo from 22·01 to 20·24. The latter centre is a consumptive resort and also a large contributor to deaths from miners' phthisis.

Milk Standard.

For a long time the Victorian dairymen have been dissatisfied with the 3·5 per cent. standard of butter fat in milk. [illegible] this standard. [illegible] of the present [illegible] to urge the [illegible] to something below the present standard.

Municipal Sanitation.

Wrightville is a small municipality near Cobar in New South Wales. The Board of Public Health recently notified the local council that a pan system of night-soil disposal would have to be established. The councillors declined to consider the matter and resigned in a body as a protest against interference in their affairs.

Obituary.

The death of Dr. John Thomson of Brisbane removes one of the oldest and best known figures in the medical profession of Queensland. Dr. Thomson was a graduate of the University of Edinburgh and a very old resident of Brisbane. He was surgeon to the hospital and principal medical officer of the Queensland military forces, besides holding many public positions of trust. He was President of the Australasian Medical Congress which assembled in Brisbane some years ago. The late Dr. Thomson possessed a genial personality, as well as sound professional insight and skill, and was very popular wherever he went. One daughter, Dr. Jean Thomson, is also a member of the medical profession and practising in the northern capital.

Medical Bill.

The medical profession in Queensland recently approached the Premier with a request that a Medical Bill should be introduced into Parliament to remedy many existing abuses. At present the question of registration is very unsatisfactory, and a practitioner may be registered after three years' study. The Premier promised to endeavour to meet the wishes of the deputation.

Drink Legislation.

Mr. Lesina, M.L.A., of Queensland, has recently returned from visiting New Zealand and says, with respect to liquor legislation in the Dominion: "In spite of passing 13 Acts, each more drastic than the last, prohibitionists are still asking for new enactments. A curious fact is that as the number of licences is decreased the convictions for drunkenness increased, and there has been gradual increase in the annual drink bill since 1895. Sly grog shops are encouraged by this legislation, and a system of perjury and police corruption has resulted which is very undesirable. Lunacy is increasing and there is a general disrespect for the law." Mr. Ranking, P.M., who was specially deputed to report on the matter for the Queensland Government, has reviewed the liquor legislation from an industrial standpoint. From the social aspect much might be said on both sides for the operation of the no-licence system. He draws the conclusion that it would be unwise to adopt the New Zealand system pending a more extended experience of its effects.

Ploughing Bee.

A somewhat novel method of obtaining funds for a hospital was adopted by the Casterton (Victoria) committee. The president induced the committee to lease 25 acres of land and then arranged with a number of neighbouring farmers to plough and sow it. 25 teams turned to the ploughing operations, which were completed in a single morning.

Melbourne Hospital.

After a good deal of hesitation the committee has consented to a request from the medical staff to construct the new hospital on a 400 bed basis, but the equipment of beds will only be proceeded with as future income may determine. The present building accommodates about 300. Another proposal from the staff has given rise to some newspaper controversy. The Melbourne Hospital has hitherto been without special departments for aural, throat, or eye work. There has likewise been no special gynæcological department. Instruction in these subjects has been obtained by students at the Eye and Ear and the Women's Hospitals. It is now pointed out that this arrangement is unsatisfactory, and the staff have requested that specialists in these subjects be appointed to the out-patient department. This request has been opposed by the committees of the two special hospitals named, and the treasurer is likely to be approached to insist on the Melbourne Hospital remaining as at present, on the ground that the new departments would constitute overlapping of hospital provision. At the recent Congress a committee was appointed to request the Government to appoint a charities board to prevent overlapping, and advantage is being taken of this attitude by those interested in the special hospitals. It is probable that a compromise of some kind will be effected, as it appears obviously absurd that the great teaching institution of the University should not be self-contained in all special departments.

May 19th.

Obituary.

DANIEL JOHN CUNNINGHAM, M.D. Edin. & Dub., F.R.C.S. Edin. & Irel., D.C.L. Oxon., F.R.S.,

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF EDINBURGH.

By the death of Professor Cunningham the University of Edinburgh has lost perhaps the most distinguished member of its medical faculty. The illness which terminated fatally on June 23rd began early last winter and rendered him unable to perform his professorial duties. In the hope of regaining health he went to Egypt in December. His condition was, however, not ameliorated by the change of climate, for while there he continued to suffer much pain. He left Egypt at the end of March and from the time of his return to Edinburgh he was confined to bed. He became steadily weaker until he died. His illness was anxiously watched by the whole profession in Edinburgh, while the hopelessness of the outlook and the knowledge that the illness was associated with much suffering elicited a widespread and a deep sympathy with him and with his family.

Professor Cunningham was in his sixty-first year at the time of his death, and before the appearance of the malady which led to his death he had the aspect of a man with the expectation of many years of vigorous life. He was, what is called in Scotland, a "son of the Manse," his father at the time of the son's birth being parish minister of Crieff, while later he became Principal Cunningham of St. Andrews. Professor Cunningham graduated in medicine at Edinburgh in 1874 with first-class honours, and two years later took his M.D., receiving a gold medal for his thesis on "The Anatomy of the Cetacea." At this time he was promoted from junior to senior demonstrator of anatomy under Sir William Turner. This position he held for six years, while at the same time he lectured on physiology at the Royal Dick Veterinary College. In 1882 he went to Dublin to fill the chair of Anatomy at the Royal College of Surgeons in Ireland, and at the end of the following year he was transferred to a similar position in Trinity College. In Dublin he at once began to make himself felt in the improvement and shaping of medical education, and raised his own department to a high level of efficiency. At the same time he contributed largely to the literature and made important additions to the knowledge of human and comparative anatomy. His "Manual of Practical Anatomy," written when in Dublin, has for many years been largely used by medical students in every school, especially by those who were determined upon an honours course. In the London schools it has become the standard text-book for the dissecting-room. To many students accustomed to the older manuals it came almost as a new revelation of anatomy, for both by the clearness—we might almost say the eloquence—of its descriptions and by its admirable directions for dissection it rendered readily accessible those difficult regions of anatomy which had rarely been thoroughly explored by the "average student." The section dealing with the abdomen is in itself sufficient to warrant this praise, both the arrangement of the peritoneum and the topography of the viscera being described in such a manner as to render their visualisation a comparatively simple matter after they had once been dissected under the guidance of the manual. The arrangement of the pelvic fascia and the dissection of the neck and brain are dealt with in an equally masterful manner, and we can hardly call to mind any text-book which has been, and will continue to be, of such practical assistance to a very large number of medical students. In 1902 the "Text-Book of Anatomy" appeared under his editorship. Amongst his more original works were his "Report on Marsupialia Collected during the Voyage of H.M.S. *Challenger*," "On the Lumbar Curve in Man and Apes," "On the Surface Anatomy of the Cerebral Hemispheres," "A Research into the Relation between Giantism and Acromegaly," and "A Memoir on the Microcephalic Idiot." He was an editor of the *Journal of Anatomy and Physiology*.

In 1903, on Sir William Turner's appointment as Principal of the University of Edinburgh, Professor Cunningham was offered the chair of Anatomy thus vacated. The offer was accepted and Professor Cunningham returned to the scene of his early work and to the chair of his former chief. His return was cordially welcomed on account of his distinction as an anatomist and his character as a man. In Edinburgh he took a leading part in the medical faculty of the University, of which he was for some years Dean. He had ideas and schemes regarding the school which had begun to get beyond the speculative stage, and his tactful handling of them will be missed. During the brief period of his occupancy of the Edinburgh chair he was one of the commissioners sent out to inquire into the medical administration during the South African war, and more recently he took a leading part in arranging the medical administration in Scotland of Mr. Haldane's scheme for the establishment of the Territorial Force. Professor Cunningham's attainments and work were more fully recognised than falls to the lot of most men, but his remarkable attainments and qualities were deeply impressed upon all who knew him. He was a Fellow of the Royal Society; he held the honorary degrees of M.D. and D.Sc. of Dublin, of D.C.L. from Oxford, and of LL.D. from both St. Andrews and Glasgow. He was at various times secretary, Vice-President, or President of the Royal Zoological Society of Ireland, of the Anthropological Section of the British Association, of the Royal Dublin Society, and of the Royal Society of Edinburgh. His was truly a life full of excellent work and of well-merited reward. He has left a mark on the two great medical schools of Dublin and Edinburgh, with which they may justly be gratified and which may be looked on as having the measure of endurance which belongs to work done as Cunningham did his. His influence was great and on every side good. Along with a quiet resoluteness of purpose he was simple and gentle in manner, kindly and friendly to all. He gained the mastery by tact and gentleness and persuasiveness, and appears never to have made an enemy.

He was a loyal and devoted friend, and his friends were devoted to him. Seldom has a death occurred in the profession in Edinburgh where the sense of personal loss has been wider and deeper than it has been at Cunningham's premature loss, and much sympathy is felt for Mrs. Cunningham and his family.

On Saturday, June 26th, the funeral took place, the interment being in the Dean Cemetery, where very many of those who once were prominent in Edinburgh life are also buried. On Sunday a memorial service was held in St. Giles's Cathedral, when the Rev. Professor Kirkpatrick, D.D., Dean of the Faculty of Divinity, preached from the text: "Clouds and darkness are round about Him; righteousness and judgment are the habitation of His Throne." The preacher said that no man was held by his colleagues in the Senatus in higher honour or warmer affection than Cunningham. "The bright and sunny temperament, the warmth of heart, the transparent simplicity that was unconscious of its own greatness, the nameless grace that was the index of beauty of spirit, endeared him to all with whom he came into contact. No one could associate with him for a little without carrying away an indelible impress of a singularly lovable personality."

An Irish correspondent writes: "The announcement of the death of Professor Cunningham has probably nowhere produced such uniform sorrow as in the Irish metropolis, which was privileged to enjoy his genial presence and enlightened teaching during a large part of his professional career. His appointment to the duplex Chair of Anatomy in the Royal College of Surgeons in Ireland in 1882 marked the initiation of a new epoch in the teaching of anatomy in Dublin. Dublin had always been noted for its facilities for the acquisition of anatomical knowledge, for Ireland out of her poverty has supplied liberally the anatomical schools of her metropolis with ample material for research in human anatomy. But at the time of Professor Cunningham's arrival a system of 'cramming' had sprung up especially in the private schools of the city, a system which had its origin in the exigencies of supplying rapidly a medical service of some sort for the British troops in the Crimean war. It is true that the leading anatomists in Dublin knew and taught their science at least as well as it was taught anywhere else in the world. But a great deal of corruption had crept in, and the skill of the grinder was a great temptation to the 'chronic' to expend as little of his own intellectual energy as possible in the acquisition of the modicum of knowledge required to satisfy the Board of Examiners. Professor Cunningham set himself at once to extinguish the methods of private tutors and copious dissecting-room demonstrations, and encouraged the student to attend the authorised lectures and to secure his practical knowledge by his own investigation of the subject. 'Practical work' became the scientific watchword of the period, and the teaching of the Dublin school was completely revolutionised on the appointment of Sir Lambert Hepenstal Ormsby as examiner in anatomy soon after the election of Professor Cunningham. A great many changes have occurred in consequence of the modifications of teaching and practice introduced by Professor Cunningham and Sir Lambert Ormsby; and the 'private schools' have all vanished. The accomplished Scotch anatomist stayed but a short time in the school which so rapidly learnt to appreciate his value, but he left behind him an ineffaceable record of work which gained him so speedily the chair of Anatomy in Dublin University."

EDMUND MARSHMAN RUSSEL RENDLE,
M.R.C.S. ENG., L.S.A.,

CONSULTING SURGEON TO THE ROYAL PLYMOUTH EYE INFIRMARY.

Mr. E. M. Russel Rendle died at his residence, Caton, Ivybridge, Devon, on June 23rd, in his seventy-seventh year The deceased was the son of the late Dr. E. Rendle of Plymouth. He was educated at Glenalmond School, and received his medical education at King's College Hospital, London. He qualified M.R.C.S. Eng. and L.S.A. in 1854 and 1853 respectively, and shortly afterwards joined his father, who was then in partnership with the late Mr. Joseph Square at Plymouth. Mr. Rendle was for many years on the staff of the Plymouth Public Dispensary, but it was in connexion with the Plymouth Royal Eye Infirmary that his chief honorary surgical work was done. He was greatly devoted to the institution, and from 1866 to 1893 he was honorary surgeon. He then became a member of the consultative staff, and in 1896 his long and valuable services were recognised by his election to the presidency of the charity. For many years Mr. Rendle was honorary medical officer to the Devon and Cornwall Orphan Asylum. He was at one time surgeon to the old South Devon Militia, now the 3rd Devonshire Regiment. Outside his professional work he took a great interest in the well-known newspaper, the *Western Morning News*. Early in the history of that paper he became one of the directors and was a managing director until 1902, when he retired. Mr. Rendle was a prominent figure in the estimation of the "Three Towns." As a practitioner his judgment was sound, and his skill of no mean order. He was always particularly kind to his poorer patients and was beloved by a large and varied number of friends, and acquaintances. He retired from practice ten years ago, and five years ago he left Plymouth to reside at Ivybridge.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Thumm, Privy Councillor and physician to the Children's Hospital at Pforzheim, who was 82 years of age, suddenly from apoplexy while at the bedside of a patient.—Dr. Alfredo Thomé de Britto, professor of medical diagnosis in the University of Bahia.—Dr. Wilhelm Muller, formerly professor of pathological anatomy in the University of Jena.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—E. W. Archer (Sections I. and II.), St Mary's Hospital; [illegible] Archer, St. Mary's Hospital; J. M. Burke, Middlesex Hospital; J. H. Clarke, St. Mary's Hospital; and H. O. West, King's College Hospital.

Midwifery.—E. W. Archer, R. J. Cyriax, and G. Holmes, St. Mary's Hospital; and H. O. West, King's College Hospital.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. M. Adam, E. W. Archer, J. Bramley-Moore, J. H. Clarke, L. Ettinger, J. A. Koch, P. N. Panton, and H. O. West.

UNIVERSITY OF CAMBRIDGE.—At the First Examination for medical and surgical degrees held recently the following candidates were successful in the subjects indicated:—

Part I., Chemistry and Physics.—M. L. Atkinson, Emmanuel; H. Bartlett, Caius; F. R. Boswell, Queens'; C. W. Bower, Caius; H. F. Brice Smith and M. Chadwick, *St. John's*; V. M. Coates, Caius, G. R. E. Colquhoun, Trinity; L. P. Costobadie, Caius; D. D. Evans and L. H. B. Evans, King's, B. J. L. Fayle, Emmanuel, L. A. Graham, Caius, G. L. Grant, Queens'; J. Hardy, Caius, R. J. Hearn, Jesus, J. H. Jordan, Emmanuel; W. H. Livens, Christ's; O. C. McCaw, Caius; J. B. McFarland, Sidney Sussex, F. W. Maunsell and S. H. Miles, Clare, H. L. Milsom, Trinity; G. Miskin, Caius, H. R. Pollock, Trinity, G. D. Read, St John's; A. P. Saint, Downing, C. H. Savory, Trinity, J. W. Sewill, Clare, [illegible] J. R. Stoddart, [illegible] broke, D. C. L [illegible]

[illegible] Cowper, Trinity, D. Crellin, C. Cunnington, Corpus Christi; [illegible] bson, Queens'; H. Dunkerley, Downing; A. T. Edwards, St. John's, D. D. Evans and L. H. B. Evans, King's; J. M. Evatt, Caius, B. J. L. Fayle, Emmanuel, L. S. Fry, King's, E. A. Gibb, Emmanuel, C. L. Gimblett, Caius; G. L. Grant, Queens', R. Hargreaves, Caius, R. J. Hearn, Jesus; J. H. Jordan, S. D. Kilner, and A. A. Lees, Emmanuel; W. H. Livens, Christ's, W. A. H. Lowry, Caius; W. M. Lupton, Clare; F. W. Maunsell, Caius, S. H. Miles, Clare, G. Miskin, Caius; C. C. Okell, St. John's, G. Y. Oliver, Magdalen; H. B. Padwick, Emmanuel; J. S. Pooley, Trinity; G. D. Read, St. John's; J. R.

Rees, King's; A. P. Saint, Downing; R. P. A. Starkie and R. Stott, Trinity; M. Tin, Downing; E. W. Todd, Trinity; D. C. C. Vey, Clare; T. T. B. Watson, Christ's; G. H. Wells-Cole, Caius; A. M. Wheeler, Sidney Sussex; and H. G. Wiltshire, Emmanuel.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates passed in the subjects indicated:—

FINAL EXAMINATION IN MEDICINE.

Part II., Surgery.—Thomas A. Hughes, Ralph T. St. J. Brooks, David Duff, Eric J. Powell, John D. Kernan, George E. Craig, Edwin B. Bate, Frederick R. Sayers, David J. Miller, Frederick G. Anderson, Charles G. S. Baronsfeather, James P. S. Dunn, Wellesley R. Allen, and Denis J. Stokes.

M.Ch. Degree.—J. Singleton Darling.

M. Dent. Sci. Degree.—Ernest S. Friel.

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—John Colgan, Jacobus M. S. Gericke, Frederick B. M'Carter, Eileen Hewitt, Hubert T. Bates, Robert A. Flood, James N. Armstrong, Georgina Revington, Robert G. Ball, Dorothy K. Milne, William E Featherstonhaugh, Edwin F. O'Connor, Jerome H. Counihan, Jevan H. Powell, Arthur P. Draper, Hugh G. Trayer, Robert H C. Lyons, Cecil Rutherford, William Frier, Oswald V. Burrows, James H. Grove-White, Richard L. Grandy, Antonie C. Redelinghuys, Humphry L. Blackley, Hugh E. Williams, and Frederick A. Burke.

Purser Medal in Institutes of Medicine.—Jacobus M. S. Gericke.

Medical Travelling Prize and Banks Medal.—Albert Stals.

Banks Prize.—John L. Phibbs.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Professor Neuberg, assistant in the Chemical Department of the Pathological Institute, is resigning his post in the Medical Faculty, having been appointed to the charge of the Chemical Department in the Veterinary School.—*Budapest:* Dr. Némath has been recognised as *privat-docent* of Forensic Mental Pathology.—*Greifswald:* Dr. Heinrich Gebb, assistant in the Ophthalmological Clinic, has been recognised as *privat-docent* of Ophthalmology.—*Halle:* Dr. Hermann Schmidt-Rimpler, who is now more than 70 years of age, is resigning the Professorship of Ophthalmology. The names of two ophthalmic surgeons have been published as having been appointed to the chair. Whether the duties of the chair are to be divided or whether one of the announcements was made in error does not as yet seem clear.—*Hamburg:* Dr. Friedrich Jessen, formerly physician to a hospital in Hamburg but now practising at Davos, has been granted the title of Professor.—*Heidelberg:* Dr. H. Kossel, Professor in the University of Giessen, has been appointed Professor of Hygiene.—*Innsbruck:* Dr. Alfred Decastello Ritter v. Rechtwahl has been recognised as *privat-docent* of Medicine. Dr. E. von Hibler, *privat-docent* of Pathological Anatomy, has been promoted to an Assistant Professorship.—*Leipsic:* Dr. Paul Sick has been recognised as *privat-docent* of Surgery.—*Prague (German University):* Dr. Friedrich L'ippich has been recognised as *privat-docent* of Physiology. (*Bohemian University*): Dr. Tobiasek has been recognised as *privat-docent* of Orthopædic Surgery.—*Rio de Janeiro:* Dr. Miguel Pareira has been appointed to the chair of Clinical Medicine.—*Rostock:* Dr. Brüning, *privat-docent* of children's diseases, has been promoted to an Extraordinary Honorary Professorship.—*Strasburg:* Dr. Kieffer has been recognised as *privat-docent* of Odontology.—*Tübingen:* Dr. E. Letsche, assistant in the Physiological Institute, has been recognised as *privat-docent* of Physiological Chemistry.—*Vienna:* Dr. Ludwig Teleky has been recognised as *privat-docent* of Social Medicine.

SCARLET FEVER AND MILK IN THE THAMES VALLEY.—The public health committee reported to the London County Council on June 29th with reference to certain cases of scarlet fever notified by the medical officer of health of Westminster which he suspected might be attributed to infected milk-supply. Other local outbreaks were notified in Chelsea and Wandsworth, and at Kingston-on-Thames and other parts of Surrey. The cases appeared to be traceable to the same wholesale supply, the company were communicated with, and they stopped the supply from the suspected depôt. On June 20th Dr. W. H. Hamer and Dr. E. Seaton, medical officer of health of Surrey, met the manager of the company and proceeded to a particular farm—the only one from which milk had been supplied to all the localities known to be involved. Inquiries disclosed the fact that five recent cases of scarlet fever had occurred in a family the members of which had consumed milk from the farm, one of the persons affected being employed at the farm. All possible steps had been taken to prevent further infection. The committee retained the services of Dr. Mervyn H. Gordon, of St. Bartholomew's Hospital, to undertake any bacteriological examinations necessary.

THE CHILDREN'S CONVALESCENT HOME, WESTON-SUPER-MARE.—The annual meeting of the subscribers to this institution, which is a branch of the Bristol Children's Hospital, was held at Weston-super-Mare on June 15th, under the presidency of Lady Smyth. The medical report stated that during 1908 323 children had been admitted. The financial statement showed an adverse balance of £87.

UNITED HOSPITALS ATHLETIC CLUB.—The United Hospitals Athletic Club's annual championship meeting took place at the Stamford-bridge ground on June 23rd, when London Hospital won the challenge shield with 59 points, Guy's Hospital being second with 55 points, and St. Bartholomew's Hospital third with 29 points. The 100 yards, high jump, throwing the hammer, long jump, and quarter mile events were all won by London Hospital.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on June 18th. There were present: Dr. F. de Havilland Hall (in the chair) Dr. J. Pickett, Dr. J. W. Hunt, Dr. St. Clair B. Shadwell, Mr. J. Brindley James, Dr. W. Knowsley Sibley, Dr. W. G. Dickinson, Dr. Frederick S. Palmer, Mr. F. S. Edwards, Dr. W. A. Dingle, Mr. H. P. Symonds (Oxford), Dr. F. J. Allan, Dr. M. Greenwood, Mr. J. F. Colyer, Mr. E. Bartlett, and Dr. J. B. Ball.

A FALSE DECLARATION OF STILLBIRTH.—An anonymous letter recently called attention at Greenwich to the case of a newly born child whose father had signed a declaration for the purpose of burial to the effect that the child was stillborn. The exhumation of the body followed, and medical evidence at the inquest held by Dr. H. R. Oswald showed that the child apparently had had a separate existence and breathed well, but subsequently had died from suffocation. One of the witnesses was an uncertified woman practising as a midwife who admitted having told the undertaker in the father's presence that the infant was stillborn, although, in fact, it was to her knowledge born alive. It was also apparent from the father's evidence that he wilfully deceived the Registrar. The jury returned a verdict of "Death from accidental suffocation."

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on June 24th, Dr. F. H. Champneys being in the chair. The following charges alleged against the midwife Emma Pitman were considered:—That having been in attendance as a midwife at a confinement on Jan. 2nd, 1909, and following days, she falsely entered in her register of cases that her last visit was on Jan. 12th, and that the condition of the mother was then good, whereas in fact she was in attendance on the mother until her death on Jan. 14th. Also that being in attendance as a midwife at a confinement, the patient suffering from persistently offensive lochia with abdominal tenderness and a rise of temperature above 100·4° F., she did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that it might be immediately forwarded to the medical practitioner, as required by Rules E. 18 and 19. A[illegible] case the Board severely censured this [illegible] charges alleged against the midwife Eliza Thompson were considered:—That being in attendance as a midwife at three confinements, and having advised in each case that medical aid should be summoned, she failed to notify the local supervising authority thereof, as required by Rule E. 20, and that she habitually neglected, after repeated warnings, to do so. After deliberating on the case the Board censured this midwife. At the ordinary meeting of the Board held on the same day, the following business, *inter alia*, was transacted. A letter from Dr. J. C. Thresh, county medical officer of Essex, as to the refusal of medical practitioners in a country district of Essex to attend when summoned on the advice of a midwife was further considered. A letter on the same subject was considered from Mrs. Gifford, honorary secretary of the Aldham, Copford, and Mark's Tey Nursing Association. The secretary, Mr. Duncan, was instructed to write that the Board reply that no blame can attach to the midwife if she strictly carries out the rules of the Board as to summoning medical assistance.

Gift to the London Hospital Medical College.—The London Hospital Medical College Endowment Fund has received a gift of £2000 through the kindness of Mr. Luther Martin, an old student of the college.

At the annual general meeting of the *London Nottinghamshire Society*, held on June 24th, Mr. Sydney Stephenson was elected president of the society for 1909-10.

The Workmen's Compensation Act.—In a compensation case heard at Newton Abbot (Devon) county court recently Judge Lush-Wilson said that even if a man had an inherent defect, such as heart disease, before an accident the employer was still liable.

The Colonial Nursing Association.—The annual meeting of this association was held at the invitation of Lady Wantage at 2, Carlton-gardens, Carlton House-terrace, W., on June 24th, when Princess Christian of Schleswig-Holstein was present. Sir Albert Hime presided in the unavoidable absence of Lord Ampthill, the President. In his plea for additional help, which is urgently required to extend the good work done by the association, the chairman remarked that the total number of nurses employed during the year was 209, of whom 62 were employed as private nurses and the remainder in Government institutions. Colonel Seely (Under Secretary of State for the Colonies), in moving the adoption of the report, paid a warm tribute to the help of Mr. and Mrs. Chamberlain. The Colonial Office, he said, had reason to be especially grateful to the association, which relieved the Government officials of the very difficult task of selecting candidates for nurses in the colonies. Colonel Sir Percy Girouard seconded the motion, and was supported by Sir H. H. Bell. The report having been carried, Sir Alfred Jones, in proposing a vote of thanks to Princess Christian for her presence, remarked that he himself would pay the deficit of £111 which was shown on the balance sheet.

Literary Intelligence.—Messrs. Rebman, Limited, announce a new book on "Accidental Injuries to Workmen with Reference to Workmen's Compensation Act, 1906," by Mr. H. Norman Barnett, with an article on Injuries to the Organs of Special Sense by Dr. Cecil E. Shaw, and a legal introduction by Mr. Thomas J. Campbell. In view of the very grave responsibility which the Act places upon medical men, and the importance of a report being correct as to diagnosis and accurate as to prognosis, a chapter has been devoted to the making of reports. Messrs. Rebman have also just issued Professor de Giovanni's "Clinical Commentaries Deduced from the Morphology of the Human Body," translated from the Italian by Mr. John J. Eyre of Rome, and the sixth edition of Mr. J. Bland-Sutton and Dr. A. E. Giles's well-known little book on the Diseases of Women, a handbook for students and practitioners. The same publishers also state that they have almost ready for immediate publication the English translation of Professor Eugenio Tanzi's "Text-book of Mental Diseases," which has been prepared by Dr. William Ford Robertson of the Scottish Asylums, Edinburgh, and Dr. T. C. Mackenzie of the Inverness District Asylum.—Messrs. Baillière, Tindall, and Cox announce that on and after July 1st they will take over the publication of all the books by Sir William Whitla, including "Materia Medica," "Practice of Medicine," and his well-known "Dictionary of Treatment," a new edition of which will be issued in the autumn. They will also in future publish Green's "Pathology and Morbid Anatomy," a tenth edition of which is now in circulation. These changes are the result of the retirement from business after more than 40 years' work of Mr. William Renshaw, the head of the old-established firm of Henry Renshaw, which will now cease to exist. Messrs. Baillière, Tindall, and Cox have also the following new works and new editions in active preparation: Dieulafoy's "Text-book of Medicine," translated by V. E. Collins, M.D. Lond; "Manual of Massage," by M. A. Elliston, L.O.S., third edition; "Practical Microscopy," by F. Shillington Scales, F.R.M S., second edition; "Aids to Analysis of Food and Drugs," by C. G. Moor, F.I.C., and W. Partridge, F.I.C., second edition; "Sanatorium Treatment of Tuberculosis," by Rufenacht Walters, M.D.; "Surgical Anæsthesia," by Bellamy Gardner, M.R.C S.; "Aids to Mathematics of Hygiene," by R. Bruce Ferguson, M.D., third edition; "Chemical Notes and Equations," by G. H. Gemmell, F.I.C., second edition; "Gynæcological Therapeutics," by S. J. Aarons, M.D.; "Incidence of Sex and Age on Disease," by J. Grant Andrew, F.F.P.S.; "Menstruation and its Disorders," by Arthur E. Giles, M.D., second edition; also a reprint of the second edition of "Minor Maladies," by Leonard Williams, M.D.

United Services Medical Society.—There will be no meeting of this society in the month of July. The next meeting will take place at the Royal Army Medical College, Millbank, S.W., on Wednesday, Oct. 13th, 1909.

St. John's Hospital for Diseases of the Skin.—The Chesterfield medal in Dermatology issued by St. John's Hospital for Diseases of the Skin, Leicester-square, London, W.C., has this year been awarded to Dr. C. A. McBride.

A Tuberculosis Exhibition at the White City.—Preparatory to the opening of tuberculosis exhibitions in various centres in England, the exhibits recently shown at the Tuberculosis Exhibition at Whitechapel, which were described in THE LANCET of June 12th, p. 1710, have been taken to the White City at Shepherd's Bush.

Donations and Bequests.—Under the will of the late Mr. James Shaw of Liverpool the Accrington Cottage Hospital will receive £500.—By the will of the late Mrs. Annie Fulton the Cardiff University College will benefit to the extent of over £10,000.—The late Miss M. Hezmalhalch has left legacies of £2000 each to the Harrogate Bath Hospital and to the Harrogate Cottage Hospital, £500 to the Leeds Hospital for Women and Children, £250 to the Leeds District Nursing Institution, and £250 to the Ida Convalescent Home at Cookridge. Large sums will also be received by the Leeds Infirmary and by the Leeds Dispensary.—The late Miss Ann Hill of Peterborough has left £2000 to the Hunstanton Convalescent Home.—Under the will of Mrs. Hely-Hutchinson of Brighton the St. Bernard's Home for Invalid Ladies, Brighton, will receive £500.—The late Dr. Edward Bland of Derby bequeathed by will £500 each to the Midland Institution for the Blind, Dr. Barnardo's Homes, and the Nottingham General Hospital; £200 to the Nottingham Children's Hospital; and £100 to the Nottingham General Dispensary.—The Royal Dental Hospital, Leicester-square, which has just completed its jubilee, has received a donation of £200 from the trustees of Smith's (Kensington Estate) Charity and £26 5s. from the Worshipful Company of Mercers.—Under the will of the late Mrs. C. S. Greenhill the following amongst other legacies have been announced: £2000 to the Royal Free Hospital, Gray's Inn-road; £1000 each to the Middlesex Hospital, the Children's Hospital, Paddington Green, and the West London Hospital, Hammersmith; £200 each to the West London Hospital Ladies' Association and the Ladies' Association of the Royal Free Hospital.—The Adelaide Hospital, Dublin, and the Royal City of Dublin Hospital will each receive £500 under the will of the late Mrs. J. Wakefield of Kildare.—The committee for the removal of King's College Hospital has received £1000 from the executors of the late Mr. C. E. Layton, being the first instalment of a legacy of £2000 bequeathed to the fund to provide for the erection of a chapel in the new hospital. A further donation of £100 has also been received from Lady Hambleden, being her twelfth contribution to the fund.—The honorary secretaries of King Edward's Hospital Fund for London have received at the Bank of England, under an order of the High Court, the sum of £7348 17*s.* 2*d.*, the residuary estate of the late Mr. Thomas John Bell, bequeathed for charitable purposes.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Sale of Margarine Bill.

THE Sale of Margarine Bill has been completely transformed by a Standing Committee of the House of Commons. The clauses prohibiting the use of colouring matter in margarine were cut out, and the only one of any importance which remained was a section imposing increased penalties on persons who fraudulently sold margarine for butter. Even that section was materially altered. As passed by the Committee it reads: "Any person guilty of an offence under any Act in respect to the sale of margarine shall be liable on conviction under the Summary Jurisdiction Acts for a first offence to a fine not exceeding £20, for a second offence to a fine not exceeding £50, or in the alternative to imprisonment with or without hard labour, for a period not exceeding three months, and for a third or any subsequent offence to imprisonment with or without hard labour for a period not exceeding six months without the option of a fine."

Mr. KILBRIDE, an Irish Member, was in charge of the Bill. One of the most striking features of the debate on it was the absence of any representative of the Government departments which might have been considered to take an interest in the shaping of the Bill. It is true that Mr. T. W. RUSSELL, the Vice President of the Irish Department of Agriculture, attended. The frauds, which the Bill was designed to check, it was said, took place in England, but as this lay quite outside the scope of his department, Mr. RUSSELL refrained from offering departmental guidance to the Committee on the amendments which were put forward. On the first day of the Committee's proceedings, some lively protests were made that no representative of the Local Government Board, the Board of Trade, or the Board of Agriculture was present. On the second day the same situation arose. It was understood that each of the three departments concerned did not admit that the Bill fell within its administrative scope. Some honourable Members warmly declared that the Committee was being treated with disrespect, and although a motion was made to adjourn the sitting the majority decided to continue the proceedings and to finish the committee stage of the Bill. This course was followed.

Metropolitan Ambulances Bill.

Sir WILLIAM COLLINS made a vain appeal to the House of Commons at the time for unopposed business on June 24th to give a second reading to the Metropolitan Ambulances Bill. His object was to have the measure sent to a committee to have the machinery to give effect to an improved ambulance service in the metropolis considered. Objection being taken to the motion for the second reading, the further consideration of the Bill was postponed.

The Central Midwives Board.

The report on the work of the Central Midwives Board for the year ending March 31st, 1909, has been presented to the House of Commons.

The General Medical Council.

A copy of "The Representations of the General Council of Medical Education and Registration of the United Kingdom to the Privy Council under Section 10 of the Medical Act, 1886," has been laid on the table of the House of Commons.

Anæsthetics Bill.

The text of Mr. COOPER'S Anæsthetics Bill is now available. It has the support of Sir WALTER FOSTER, Sir WILLIAM COLLINS, Sir JOHN BENN, Mr. ACLAND ALLEN, Mr. BARNES, Dr. V. RUTHERFORD, Mr. BERTRAM STRAUS, and Mr. CARR-GOMM. Its object is to regulate the administration of anæsthetics, and, although drawn on similar lines to the Bill on the same subject recently withdrawn by Mr. COOPER, it differs from it in regard to its treatment of dentists. A memorandum attached to the Bill states that it is designed to require a medical practitioner or a dentist applying for registration on or after Jan. 1st, 1912, to submit evidence of having received practical instruction in the administration of anæsthetics, and to prohibit any person not a registered medical practitioner or a registered dentist administering an anæsthetic except under certain conditions.

Clause 1 of the Bill runs as follows: "On and after the first day of January one thousand nine hundred and twelve, no person shall be registered under the Medical Acts or the Dentists Acts in respect of any qualification referred to in any of those Acts unless he shall have produced evidence that he has received theoretical and practical instruction in the administration of anæsthetics."

The second clause relates to the penalties attaching to the administration of anæsthetics by unauthorised persons. Its text is as follows:—"Any person not a registered medical practitioner or a registered dentist who shall administer or cause to be administered to any other person, by inhalation or otherwise, any gas or vapour, or drug, or mixture of drugs, solid or liquid, with the object of producing unconsciousness during any medical or surgical operation, examination, act, or procedure, or during childbirth, shall be liable on conviction before a court of summary jurisdiction for such offence, to a penalty not exceeding ten pounds, and, in the case of any subsequent conviction, to a penalty not exceeding twenty pounds: Provided that a person shall not be liable to a penalty under this section if in conducting such administration he was acting under the immediate direction and supervision of a registered medical practitioner or a registered dentist, or if the circumstances attending the administration were such that he had reasonable grounds for believing and did believe that the delay which would have arisen in obtaining the services of a registered medical practitioner or a registered dentist would have endangered life."

Clause 4 lays down that "any registered medical practitioner who gives a certificate of death in the case of any person dying while under the influence of an anæsthetic shall be liable, on summary conviction, to a penalty not exceeding five pounds."

The Registration of Nurses.

Delegates from four organisations interested in the registration of nurses attended a conference in one of the committee rooms of the House of Commons on June 28th. As a result of their deliberations with several Members of Parliament who have taken an interest in the subject, a representative committee has been appointed whose duty it will be to undertake the drafting of a Bill embodying a scheme of registration applicable to all parts of the United Kingdom, which may be accepted by all the organisations. Lord AMPTHILL was in the chair, and amongst the Members of Parliament present were Mr. MUNRO FERGUSON, Mr. CLELAND, and Mr. FINDLAY, all of whom have been identified with various proposals for the registration of nurses. Amongst the delegates of the Society for Nurses Registration were Lady HELEN MUNRO FERGUSON, Miss HALDANE, Dr. J. WALLACE ANDERSON, and Dr. BEDFORD FENWICK. The delegates from the Royal British Nurses' Association included Dr. W. BEZLY THORNE, Dr. COMYNS BERKELEY, Mr. JOHN LANGTON, Mr. ARTHUR E. J. BARKER, and Sir WILLIAM MACEWEN. From the Association for the Registration of Nurses in Scotland came Professor J. GLAISTER (Glasgow), Dr. J. O. AFFLECK (Edinburgh), Dr. G. R. LIVINGSTON (Dumfries), Dr. J. M. THOM (Glasgow), and Dr. D. J. MACKINTOSH (Glasgow). An Irish association was represented amongst others by Lady HERMIONE BLACKWOOD. There was also a large contingent of ladies representing these organisations. Nearly two and a half hours were spent in discussing various aspects of the subject of registration. Such matters as the need for united action in the promotion of a Bill and the desirability of holding a simultaneous qualifying examination at centres throughout the kingdom were discussed at length. Ultimately the conference found itself in sufficient agreement to proceed to the appointment of a committee of 20 members—five from each association—who will undertake the drafting of a Bill. It is hoped that it may be found possible to frame it on lines which will carry the united support of the organisations which were represented. The intention is to present this measure to Parliament next year.

HOUSE OF COMMONS.

THURSDAY, JUNE 24TH.

Tuberculosis in Ireland.

M[illegible] Secretary to the Lord Lieutenant of I[illegible] in Ireland last year from tubercul[illegible] of the population; and would he give the same figures for the preceding two years.—Mr. BIRRELL replied: I am informed by the Registrar-General that the number of deaths in Ireland in 1908 from all forms of tuberculous disease was 11,293, or 2·6 per 1000 of the estimated population. The numbers in 1906 and 1907 were 11,756 and 11,679 respectively, or 2·7 per 1000 of the population.

The Pharmacy Act, 1908.

Mr. SNOWDEN asked the Secretary of State for the Home Department whether he was aware that town councils were continuing to license traders to sell poisonous preparations under the Pharmacy Act, 1908, where ample facilities existed; that the Halifax town council had licensed a firm of seedsmen for premises within 100 yards of nine [illegible]gh this firm had been successfully prosecuted [illegible] poisons; was he aware that the town council of [illegible] a trader for the purpose against the advice of the borough medical officer and borough coroner, that in this case it was admitted that existing facilities were ample, but that the application was granted on the ground that the applicant was an esteemed townsman who had been mayor of the borough; and whether he would take steps to stop this misuse of powers by town councils.—Mr. GLADSTONE answered: I understand from the Privy Council Office that it continues to receive complaints in this matter, and that it is making inquiry of the town council of Barnstaple; but I must point out that the question whether there are reasonable facilities in any district is one under the Act for the discretion of the local authority so long as it does not infringe the terms of the Act, and that neither the Privy Council nor the Home Office is empowered to interfere.

Children suffering from Favus.

Mr. RUPERT GUINNESS asked the Secretary of State for the Home Department whether children suffering from favus arriving from Russia and other Eastern countries were rejected by the Immigration Board at the Port of London.—Mr. GLADSTONE replied: During the last three years the London Immigration Boards have refused leave to land to four aliens from Russia, including one child of four years, whose parents were rejected from want of means, who had been certified by the medical inspector to be suffering from scalp disease, though in none of these cases was the disease specifically described as favus. I have no doubt that the Immigration Boards would, as a general rule, regard that disease as a proper cause for refusing leave to land.

Mr. RUPERT GUINNESS: Will the right honourable gentleman tell us whether he will consider the advisability of making it more difficult for these cases to come in in ships which are not inspected?

Mr. GLADSTONE: That is a matter which I have already under consideration.

Education (Provision of Meals) Act.

Answering Mr. SUMMERBELL, Mr. C. P. TREVELYAN (Parliamentary Secretary to the Board of Education) said that the Board had no complete statistics as to the number of education authorities who had in one way or another taken action under the Education (Provision of Meals) Act, but information was being collected on the subject. The Board had a list of the authorities who had been authorised to spend money out of the rates on the purchase of food.

MONDAY, JUNE 28TH.

Experiments on Living Animals.

Mr. GEORGE GREENWOOD asked the Secretary of State for the Home Department whether his attention had been called to the statement made by the inspector of experiments on living animals in the returns showing the number of such experiments during the year 1908 to the effect that one licensee who held Certificate B, authorising exposure to X rays and [illegible] carried out [illegible] state the n[illegible] of the expe[illegible] he proposed [illegible] tion of the [illegible] ments were 42 in number. Their nature is stated in the report and is quoted in the question. They were not of a severe character and [illegible] if the licensee had [illegible] The error of the [illegible] extent of his two [illegible] call for legal pro- [illegible]

Births, Marriages, and Deaths.

BIRTHS.

Gavin.—On June 22nd, at the Medical Mission Home, Anand, Western India, the wife of Neil M. Gavin, F.R.C.S. Edin., of a son.

Price.—On June 25th, at The Croft, Orpington, Kent, the wife of C. E. Price, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

Cunningham—Clarence.—On June 17th, at All Saints, Chardstock, by the Rev. E. A. Midwinter, Vicar of St. Paul's, Marylebone, assisted by the Rev. A. W. Bull, Rector of the Parish, and the Rev. J. E. B. Brine, Vicar of Studley, Oxford, John Francis, eldest son of J. K. Cunningham, of Sec Tor, Axminster, to Phyllis Lovell, youngest daughter of L. B. Clarence, of Coaxden, Axminster, late Judge of the Supreme Court, Ceylon.

Girdlestone—Chatterton.—On June 26th, at the parish church of Wimbledon, Gathorne Robert Girdlestone, M.A., B.M. Oxon., M.R.C.S., to Ina Mabel, second daughter of George Chatterton, J.P.

Guthrie—Cox.—At St. Peter's Church, Rock Ferry, on June 26th, 1909, by the Rev. W. L. Paige-Cox, M.A., Alverly Edge, uncle of the bride, assisted by the Rev. T. J. Evans, M.A., Rock Ferry, Vicar of the Parish, Thomas Mansfield Guthrie, M.B., Rock Ferry, eldest son of the Honourable Lord Guthrie, one of the Senators of the College of Justice, to Evelyn May Spear Cox, eldest daughter of the late Arthur S. Cox, Rock Ferry, and of Mrs Cox, 74, Rock-lane West, Rock Ferry, and granddaughter of the late William Paton, Esq., Rock Ferry. At Home, 233, Bedford, Rock Ferry, 6th to 11th September inclusive.

Hosegood—Lewis.—On June 22nd, at St. John's Church, Blackheath, Samuel Price Hosegood, M.R.C.S. Eng., L.R.C.P. Lond., to Dorothy Margaret, widow of the late Robert Lewis.

Sington—Cohen.—On June 30th, at Liverpool, Harold S. Sington, M.D., M.R.C.S., L.R.C.P., of 23, Cleveland-gardens Hyde Park, to Ruth Louise, younger daughter of Mr. and Mrs. Louis S. Cohen, of The Priory, St. Michael's Hamlet, Liverpool.

DEATHS.

Wilmot.—After a short illness, in his 67th year, Alfred Edward Wilmot, M.R.C.S., L.R.C.P., J.P., of Burnham [illegible]

Woolrabe.—At Melbourne, on May 8t[illegible] (Peggy), beloved wife of Frederick W[illegible] Edin., D.P.H., of Riccarton, near Cam[illegible] Officer to the Government of Queensland, Brisbane.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"PHARMACY" EXTRAORDINARY.

WE do not remember to have noticed previously quite so impertinent an announcement as appeared in the *Daily Graphic* of June 28th, for it purported to emanate, not from one of the pirates of medicine, but from a man who owed the greater part of his living to its qualified practitioners whose skill he proposed to exploit. The advertisement ran in these words:—

> PRESCRIPTIONS (guaranteed copies) by eminent London and Continental Specialists; any disease; post free 2*s.* 6*d.* from retired West End pharmacist, Robertson, 6, Elmbourne Road, London, S.W.

The question of the ownership of prescriptions is a vexed one, but at any rate copyright in them cannot be vested in the man who makes them up. The position of the huckster is also curious. If he seeks to add to the attractions of his wares by disclosing to his customers the identity of the "London and Continental Specialists," from whom he had them in trust, it should not be hard for one of those gentlemen to obtain an injunction to prevent him from continuing his curious trade. If he does not give the names of the authors of the prescriptions how is the public to know the truth of his claims? Be all this as it may, the gross breach of professional decency which the advertisement implies is apparent, and deserves the notice of the Pharmaceutical Society of Great Britain, even though the "West-End pharmacist," having retired, has no further respect for its authority. But perhaps the chief feature of the advertisement is its fatuity, for although the advertiser offers prescriptions for "any disease" he does not suggest the method by which the disease may be recognised by its victim, neither does he show any authority to claim the skill which can match a disease with its appropriate prescription. In making these remarks we do not, of course, forget that the advertisement carries no proof of its *bona fides*, and for the credit of the profession of pharmacy we would prefer to regard it as the device of an ordinary adventurer to make money without doing any work for it.

ACIDOSIS AND DIABETES: A SUGGESTION.

To the Editor of THE LANCET.

SIR,—When the state of acidosis develops in diabetes mellitus alkalies are given in the form of a sodium salt alone or of a potassium salt alone, but never, as far as I can learn, are the alkalies combined.

The alkalies have two uses: they serve to neutralise obnoxious acids, and they replace what is abstracted from the tissues and the body fluids. The sodium salt will refurnish the fluids mainly, and the potassium salt the tissue cells. The sodium salt will not give much help to the nervous system, nor the potassium salt to the fluids, where, in the case of the blood, the sodium plays the essential part in respiration. Thus coma, which I presume to have a double origin—the state of the nerves and the failure of gaseous exchange—cannot be so efficiently retarded with one base as with two. But in diabetes there is deprivation of all four of the principal bases, and though the calcium and magnesium come mainly from the bones their loss elsewhere must result in derangement. Is there not, then, some reason for trying an experiment in which all four bases are used?

I am, Sir, yours faithfully,

Newcastle-on-Tyne, June 19th, 1909. W. T. GIBSON, A.R.C.S.

⁂ Our correspondent's suggestion is interesting, but in view of the marked depressant properties of potassium ions when injected intravenously great care would be necessary in regard to this base.—ED. L

MEAT WARRANTY AND INSURANCE AGAINST TUBERCULOSIS.

MUCH has been heard of late on the subject of the meat warranty. In many quarters the farmers and butchers have adopted a system of mutual insurance, and the arrangement seems to be working satisfactorily. Lewes, the county town of Sussex, provides an example of this. At the market here something like 5000 bullocks and cows and over 3000 calves were sold during the year just ended, and the figures submitted to the annual meeting in connexion with the scheme of insurance against tuberculosis show that during the 12 months the sum of £258 1*s.* 6*d.* was collected from the sellers, while £111 0*s.* 6*d.* was paid out, including expenses, leaving a balance of £146 in hand. The payments were made for the following items:—

	£	*s.*	*d.*
3 cows and 3 parts of cows	46	10	5
13 pigs condemned...	22	13	1
1 steer and part of a runt steer	21	3	6
Part of 1 heifer...	10	13	0
1 calf	2	16	3
13 pigs' heads	1	13	6

Practically the whole of the money received from the insurance of cows was paid away and the balance in hand was almost entirely made up by the contributions received in respect of steers, heifers, and calves. Notwithstanding the thousands of animals passing through the market there was a very small percentage affected with tuberculosis. Pending legislation on meat warranty, the mutual insurance scheme appears excellent in more ways than one, and its adoption should certainly help to safeguard the public against tuberculosis. The Government has recognised the principle of compensation, but has not yet gone so far as to provide the money out of the Exchequer, and whatever be the future law on the subject it appears probable that a system of insurance will be adopted by the class that may be rendered liable to financial loss under its provisions.

THE HEALTH OF GERMAN EAST AFRICA.

EIGHT years have elapsed since the last British consular report on German East Africa was published, so that more than usual interest attaches to the new one recently laid before Parliament. It is written by Mr. Vice-Consul Douglas Young, who mentions incidentally that the white population on Jan. 1st, 1908, was estimated at 2845, as compared with 2629 on the same date in the preceding year; this represents an average of one to 135 square miles. In a newly colonised country possessing an area of 384,169 square miles, a census taking of the native population is obviously an impossibility, but it is roughly calculated at between 8,000,000 and 10,000,000. Both the mortality and the birth-rate are believed to be greater on the coast than in the interior. On the coast this population is chiefly composed of Swahilis, a hybrid race of Arab and native strain, while the interior is peopled by various tribes of the Bantu race. The climate on the coast and in the lowlands is hot and enervating and in some places dangerous to Europeans, but the town of Dar-es Salaam may be considered as comparatively healthy, thanks to its favourable situation in regard to the monsoons and to the good work done by sanitary authorities. The highlands of the interior are for the most part healthy and suitable for European settlement. The highest reputation in this respect is enjoyed by the Usambara highlands behind Tanga and by the Moschi district at the foot of Mount Kilimanjaro, which have consequently become the chosen localities of European planters The chief diseases which claim victims among the white population are malaria, blackwater fever, and dysentery. The most prevalent diseases among the natives are small-pox, chicken-pox, malaria, and ankylostomiasis which constitutes a serious danger to the colony. It first broke out in 1906 in the coastal districts, especially Tanga and Rufiji, and spread rapidly, claiming many victims. The number of cases treated quarterly in the native hospital at Dar-es-Salaam alone has risen from an average of 20 to over 90 in recent years The disease, which appears to be a particularly insidious one, is being energetically met by the thymol treatment, but the work of the medical authorities is rendered the more difficult by the ignorance and indifference of the natives in regard to sanitary precautions. German East Africa has remained remarkably free from outbreaks of plague, and the success with which the introduction of the disease by sea from India and South Africa has been prevented is undoubtedly due to the stringent quarantine measures which are adopted against the shipping of infected ports. Sleeping sickness constitutes a grave danger to the colony, and is regarded by the Government as so serious a menace that no effort or expense is being spared to combat the disease. Following upon the researches made by Professor Koch in Uganda, expeditions have been organised to Ujiji and Shirati, the centres of the infected districts, and a regular plan of campaign has been adopted against the scourge in the organisation of segregation camps, the clearing of vegetation from the shores of the lakes, and the destruction of crocodiles and other reptiles on which the infection-bearing fly (Glossina palpalis) thrives. Little doubt is felt that sleeping sickness was originally introduced into German East Africa from British and Congolese territory, first of all to the shores of Victoria Nyanza, notably at Shirati and Muanza, whence it gradually spread eastward and southward to Lake Tanganyika, where the presence of the dreaded Glossina palpalis has been detected as far south as the mouth of the river Mlagarassi. In consequence of this it is proposed to open three new stations on Lake Tanganyika. Much good is expected to result from the Anglo-German agreement signed on Oct. 27th, 1908, for the combating of the disease. Both Dar-es-Salaam and Tanga now possess commodious and well-equipped hospitals for Europeans, situated in the best positions available as regards the monsoons They are staffed by Government medical officers and nursing sisters, the Sewa Haji Hospital in the former town having been founded by the munificence of an Indian in 1893 In other places on the coast and at interior stations the medical needs of Europeans and natives alike are cared for at the various mission stations. The Leinhardt sanatorium, ideally situated at Wugire in West Usambara, nearly 4000 feet above sea level, provides a place of rest and recuperation for invalid and convalescent Europeans at a reasonable charge. The town of Dar-es-Salaam is fully described in the report, which speaks most favourably of its situation and sanitary supervision.

CHLORODYNE.

OUR attention has been drawn to a statement that Collis Browne's chlorodyne contained appreciable traces of prussic acid The proprietors deny that such is the case, and a recent chemical analysis made by ourselves of a sample purchased in the open market justifies this denial. We could find no trace either of hydrocyanic acid or of any cyanide, the separation and identification of which is a simple

matter, extreme delicacy of detection being also possible. It may be pointed out that the tinctura chloroformi et morphinæ composita of the Pharmacopœia contains hydrocyanic acid, as does also the not official liquor chloroformi compositus, but in the chlorodynum of the British Pharmacopœia codex hydrocyanic acid is omitted. According to analyses published in pharmaceutical works some years ago chlorodyne contained hydrocyanic acid, but Martindale (Extra Pharmacopœia, 13th edition, 1908) says: "We doubt whether hydrocyanic acid is now an ingredient," and according to our recent analysis the ingredient no longer appears. Chlorodyne comes, therefore, under Part 2 of the Schedule of the Pharmacy Act, 1868, and not under Part 1, which includes hydrocyanic acid.

GIVING A TRADE A BAD NAME.

His honour Judge Smyly, when hearing judgment summonses at the Shoreditch county court recently, seems to have been a little alarmed as well as puzzled by the wife of a debtor, who was understood to say that her husband carried on the trade of "a skull maker." On the learned county court judge inquiring further as to what he termed the "gruesome business," and particularly whether it kept the manufacturer busy, a point material in ascertaining his means to pay, he was reassured by the explanation that the manufacture was of "sculls for boats," at which he expressed relief.

BEE DISEASE.

THE Board of Agriculture and Fisheries desire to warn all bee-keepers that an outbreak of disease believed to be identical with the Isle of Wight bee disease has occurred in several hives in Buckinghamshire. This disease, which has destroyed almost all the bees in the island from which it takes its name, is due to a bacillus closely resembling the bacillus of plague and no remedy for it is known. It is of the utmost importance, therefore, that bee-keepers should take every precaution to prevent the disease spreading, and they are strongly advised to keep a careful watch for any signs of its appearance. A full description of the disease was published in the *Journal of the Board of Agriculture* for February, 1909, and bee-keepers who find symptoms of disease corresponding to the description there given should communicate with the Board of Agriculture and Fisheries, 4, Whitehall-place, London, S.W.

NON-ALCOHOLIC GALENICALS.

IN a leading article under the above heading in THE LANCET of June 19th, 1909, p. 1764, reference was made to the opportunity which the imposition of increased taxes on alcohol afforded of reducing to a minimum the use of alcoholic preparations of drugs without loss of therapeutic efficiency or of what is known as pharmaceutical elegance. Mr. W. Martindale of 10, New Cavendish-street, London, W., points out that a certain amount of discrimination should be used in employing glycerine as a substitute for alcohol, since all drugs are not suitable for glycerine extraction. When, for example, resinous drugs have to be extracted glycerine is not admissible, but if the active ingredients are soluble in water they are in most cases soluble in glycerine also. In regard to alkaloids, it was found desirable to employ glycerine acidulated with a small percentage of acetic acid. Under the title of "glycetracta" a number of quite elegant preparations are made on the lines indicated, and according to some specimens we have examined the results are distinctly satisfactory. Mr. Martindale points out that such preparations must contain at least 25 per cent. of glycerine to preserve them. The preparations are described in the Extra Pharmacopœia (thirteenth edition), and among those examined were belladonna, catechu, calumba, cinchona, colchicum, ergot, gentian, hyoscyamus, krameria, senna, taraxacum, all representing standardised preparations which are miscible with water (which is not the case with some of the alcohol preparations), palatable, and, of course, distinctly cheaper than the corresponding alcohol tinctures.

◆

W. E. H.—The best text-book on Hygiene in German of the description mentioned is "Prausnitz, Grundzüge der Hygiene," published by Messrs. Lehmann at Munich at the price of M.9.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1909, which was completed with the issue of June 26th, are given in this issue of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

matter, extreme delicacy of detection being also possible. It may be pointed out that the tinctura chloroformi et morphinæ composita of the Pharmacopœia contains hydrocyanic acid, as does also the not official liquor chloroformi compositus, but in the chlorodynum of the British Pharmacopœia codex hydrocyanic acid is omitted. MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1909, which was completed with the issue of June 26th, are given in this issue of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only *those subscriptions* which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

is necessary to set some boundaries, and I shall confine my inquiry to extraction with iridectomy ("combined" extraction), extraction without iridectomy ("simple" extraction), and extraction in the capsule. I may remark at the outset that the order in which I have enumerated the operations is, in my opinion, that of diminishing order of applicability to the ordinary cases of senile cataract.

One step is common to all the *methods—viz., the formation* of a section or incision. By well-nigh universal consent this is now made upwards, in or close to the apparent corneo-scleral margin. All are agreed that it should not exceed half the circumference of the cornea, that only in exceptional circumstances is so large a section necessary, but that too large a section is a trivial fault compared with one too small. A purely corneal section has been abandoned by most surgeons, and a peripheral scleral section is contraindicated owing to increased risks of prolapse of the iris; it is now customary to place the incision just sufficiently peripheral to ensure the formation of a conjunctival flap. This may be insignificant at the sides but increases gradually in width as the vertical meridian of the eye is reached. So uniform is the consensus of opinion upon the formation of the section and conjunctival flap that it would not repay us to spend time now on the consideration of details of relatively slight importance.

Iridectomy in some form or other is common to the combined operation and to extraction in the capsule as prominently advocated at the present day by Major Henry Smith, I.M.S., of Jullundur. The object of iridectomy is to allow a free passage of aqueous from the posterior chamber to the anterior chamber, thus reducing the manifold dangers of prolapse of the iris to a minimum. For this purpose it is essential that *the aperture in the iris should be large.*

It is especially requested
having a medical inter

duced by Bell Taylor, and has (printed on thin Schweigger, Pflüger, Kuhnt, Hess, and other prominent ophthalmologists. It will be seen that this device fulfils the main requirement of iridectomy with much less mutilation and with the retention of the circular pupil unimpaired. It is sometimes performed unintentionally in making the section if the aqueous escapes too rapidly. It has even been suggested that the iridectomy should always be effected deliberately in this manner! It is needless to point out that, apart from the pain experienced, leading to instability of the patient, there is no adequate control under these conditions over the amount of iris removed. If a button-hole be formed during the section the lens will very probably present in the aperture when its expression is being proceeded with. Difficulty will then be experienced in delivering the lens and probably it will be necessary to snip through the bridge of iris. If a small peripheral iridectomy is deliberately adopted it should be done after the lens has been extracted as in simple extraction. The periphery of the iris is then gently drawn out of the wound and the smallest possible fold is snipped off with de Wecker's scissors. The aperture in the iris is peripheral, so that it is almost entirely hidden by the sclerotic, and in any case is completely covered by the upper lid, while at the same time sufficient drainage from the posterior into the anterior chamber is provided for. There are other noteworthy advantages; *indeed, there are nearly* all the advantages of simple extraction without the drawbacks. Prolapse of *iris is less* likely to occur than in simple extraction, and it is quite unlikely that capsule will be left entangled in the wound, a decided drawback to extraction with the ordinary *form of* iridectomy. I can confirm the advantages of this method from personal experience, and I feel strongly that it is worthy of more extended use than it has hitherto had.

matter, extreme delicacy of detection being also possible. It may be pointed out that the tinctura chloroformi et morphinæ composita of the Pharmacopœia contains hydrocyanic acid, as does also the not official liquor chloroformi compositus, but in the chlorodynum of the British Pharmacopœia codex hydrocyanic acid is omitted. According to analyses published in pharmaceutical works some years ago chlorodyne contained hydrocyanic acid, but Martindale (Extra Pharmacopœia, 13th edition, 1908) says: "We doubt whether hydrocyanic acid is now an ingredient," and according to our recent analysis the ingredient no longer appears. Chlorodyne comes, therefore, under Part 2 of the Schedule of the Pharmacy Act, 1868, and not under Part 1, which includes hydrocyanic acid.

GIVING A TRADE A BAD NAME.

His honour Judge Smyly, when hearing judgment summonses at the Shoreditch county court recently, seems to have been a little alarmed as well as puzzled by the wife of a debtor, who was understood to say that her husband carried on the trade of "a skull maker." On the learned county court judge inquiring further as to what he termed the "gruesome business," and particularly whether it kept the manufacturer busy, a point material in ascertaining his means to pay, he was reassured by the explanation that the manufacture was of "sculls for boats," at which he expressed relief.

BEE DISEASE.

THE Board of Agriculture and Fisheries desire to warn all bee-keepers that an outbreak of disease believed to be identical with the Isle of Wight bee disease has occurred in several hives in Buckinghamshire. This disease, which has destroyed almost all the bees in the island from which it takes its name, is due to a bacillus closely resembling the bacillus of plague and no remedy for it is known. It is of the utmost importance, therefore, that bee-keepers should take every precaution to prevent the disease spreading, and they are strongly advised to keep a careful watch for any signs of its appearance. A full description of the disease was published in the *Journal of the Board of Agriculture* for February, 1909, and bee-keepers who find symptoms of disease corresponding to the description there given should communicate with the Board of Agriculture and Fisheries, 4, Whitehall-place, London, S.W.

NON-ALCOHOLIC GALENICALS.

IN a leading article under the above heading in THE LANCET of June 19th, 1909, p. 1764, reference was made to the opportunity which the imposition of increased taxes on alcohol affor[illegible] reducing to a minimum the use of alcoholic preparation[illegible]

is necessary to set some boundaries, and I shall confine my inquiry to extraction with iridectomy ("combined" extraction) … which had supervened … the first time 18 months ago (Christmas, 1907). He had a chancre when about 26, but has … his wife has had eight healthy … 15 he has had attacks of migrai… scotoma of the typical zigzag pattern (here is a sketch he has made of it), followed by headache lasting an hour or so. He has, however, had an otherwise healthy life as a clerk, and never had any convulsive attack till after he was 60. The epileptic fits are of some severity and appear to have all the characters of idiopathic epilepsy. First there is a visual aura, with flushing of the face, "the vision becomes dim, everything seems on the move," and zigzag lights appear; then he loses consciousness completely. He becomes rigid, and "struggling movements" of the limbs ensue. At times he has bitten his tongue, has had "foaming at the mouth," and micturated involuntarily. The fits last from half an hour to an hour and then he recovers. He has had one such fit every four or five weeks during the past 18 months—nearly always the first thing in the morning. The aura of these fits is interesting. In the main, you will observe that it is the same zigzag visual aura which has preceded the attacks of headache almost throughout life. Sometimes, as in idiopathic epilepsy, the aura occurs alone; sometimes during the past 18 months it was followed by convulsions. In the latter case the aura is associated with visible flushing of the face and a feeling of fulness in the head. He says: "When these fits come on I feel hot in the face and my head feels as though I had been stooping." This flushing of the face also occurs at other times. My colleague, Dr. James Mackenzie, to whom

under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

duced by Bell Taylor, and has … (printed on thin … Schweigger, Pflüger, Kuhnt, Hess, and other prominent ophthalmologists. … It will be seen that this … exion with this case is *idiopathic epilepsy*, and the characters of this patient's seizures conform to that malady. But the most important feature of idiopathic epilepsy is that it is due to something which is peculiar to the individual; something which is born with him or her and lasts throughout life. All authorities are agreed that true epilepsy starts for the first time in youth and the tendency lasts throughout life. Personally, I do not believe idiopathic epilepsy ever comes on for the first time in the latter half of life. In all my experience here and at the Paddington Infirmary and Workhouse, where I had 600 to 800 old people ill or well constantly under my care, I never saw a case of undoubted epilepsy (*grand mal* or *petit mal*) occurring for the first time in the latter half of life. Undoubtedly, when one or two true attacks have occurred in early life they may recur after a long interval. But there is no history of previous fits in this case at any time prior to the age of 60.

2. *Hysterical convulsions* may supervene almost at any age though they are commonest about the evolution and involution of the sexual functions. They are practically limited to the female sex; they are generally initiated by some emotional upset and start with some emotional outburst like crying and laughing; there is nearly always a history of previous nervous attacks or other evidence of the hysterical diathesis. But this case does not conform to hysterical attacks of any kind.

3. *Intracranial syphilis* is the most frequent cause among my out-patients of convulsive fits occurring for the first time in persons over 30 years of age. Sometimes these are due to a gummatous deposit in or upon the brain, sometimes to a more or less localised meningeal thickening, sometimes to a

without some associated cardiac failure on the one hand, or cardiac hypertrophy on the other.

13. *High blood pressure and cardio-arterial hypermyotrophy* may undoubtedly give rise to convulsive seizures and other head sensations occurring for the first time in advanced life. I am not aware whether any observations have been made on the blood pressure in epileptic and other convulsions—these would be very important and interesting—but I have seen many cases of very high blood pressure and cardio-arterial hypermyotrophy, without other defects, attended by convulsions. Both of these circulatory derangements undoubtedly exist in A. B., and I believe them to be the cause of his convulsive attacks. The history and physical signs of his case exclude all the other possibilities. Uræmia is the only other cause worth discussing and uræmic convulsions would hardly recur for 18 months, without some definite evidence of renal disease; there is no albumin or casts and the urine is only limpid, as in all cases of high blood pressure. I shall put him on treatment to lower the blood pressure and will report to you the result at our next meeting.

This case would probably still be regarded by some as one of "chronic Bright's disease," but I think this name should be reserved for cases in which there is definite evidence of renal disease as the primary and principal malady. Here all the symptoms are circulatory and the case may, in my view, be briefly expressed as one of cardio-arterial hypermyotrophy and high blood pressure consequent on a long series of constantly recurring high tension such as would be produced by his vaso-motor defect (scintillating scotoma and headaches) throughout life, coupled, perhaps, with toxæmia. It is not sufficiently recognised that renal disease is not the only cause of high blood pressure. One of the first [illegible] ches into arterial disease [illegible] 6–92 was the fact that ma[illegible] or other consequences of high blood pressure presented absolutely healthy kidneys. I wish to protest once more against including all cases which present high blood pressure, cardio-arterial hypermyotrophy, and urine of low specific gravity with an occasional trace of albumin, in the category of chronic Bright's disease. High blood pressure, as Sir Thomas Clifford Allbutt has often insisted, is a definite pathological condition with a sufficiently definite group of symptoms to receive a definite name—hyperpiesis is the name he suggested. Among the *causes* of hyperpiesis renal disease is certainly one, but there are also many toxins produced within the body, such as those of gastric and intestinal origin, or introduced from without, such as lead, which ca[illegible] disease. Urine of low [illegible] ith high blood pressure, [illegible] h blood pressure (no matter what is the cause in operation) When old people go out of doors in very cold weather their blood pressure goes up and their urinary specific gravity goes down. Pathological and long-continued high blood pressure (no matter what its cause) is often attended by a trace of albumin in the urine, and I even go so far as to believe, though I am not yet in a position to prove it, that some of the conditions we call contracted granular kidney are a consequence, rather than a cause, of long-continued or recurrent high blood pressure. Among the *consequences* of constantly recurrent high blood pressure is, as I have shown,[3] a slight but definite increase in the muscular tunic of all the arteries, and that this muscular tissue may become faintly granular and rigid, which leads not only to its non-adaptability to alterations in posture as I have just mentioned, but it also leads to cardiac hypertrophy. Then follows a struggle or opposition between the heart on the one hand and the arterial system on the other. That is what is now going on in our patient, in whom at present the heart is winning. In course of time one or other must accept defeat (degeneration and dilatation) unless in the meanwhile rupture takes place somewhere. If his vessels will dilate ever so little he will lose his symptoms and pass to a comfortable old age.

14. There is yet one more cause of convulsions supervening for the first time in advanced life—*Adams-Stokes disease* or *Heart block*. It is a morbid condition, first described by Adams in 1827 and more fully in 1836 by Stokes. It is characterised by a permanently slow pulse with syncopal and epileptiform attacks. It is due to a defective cardiac action. Dr. Mackenzie has shown, by tracings taken on the jugular vein, that although the auricle may be contracting, say, 80 to the minute, the ventricle may contract only 40 or less, missing one or more alternate beats. The condition is probably due to fibrosis or some other defect in the bundle of His, which normally transmits the cardiac stimulus from auricle to ventricle. The patient may come to you for dyspnœa or other cardiac symptoms or for epileptic attacks. A. B. has not got this condition. Less severe attacks, more of a syncopal type, may occur, as illustrated in the patient whom I now show you, aged 53, and who has only had one such attack. His pulse has always averaged 45, and his blood pressure at one time averaged 195. His case, I think, also illustrates the value of the high potential current in cases of high blood pressure.

TREATMENT.

By way of *summarising the pathology* of the various forms of syncopal, vertiginous, and epileptiform seizures which occur for the first time in advanced life my experience among the aged has led me to the following conclusions:—

1. That idiopathic epilepsy never arises for the first time in advanced life.

2 That at least nine-tenths of these syncopal, vertiginous, and epileptiform seizures are circulatory in origin.

3. That senile syncope is generally due to cardiac failure and low blood pressure.

4. That senile vertigo and similar head sensations (postural vertigo, interruptions of thought, &c.) are due to the disturbances of the regulator mechanism of the arteries in different parts of the body owing to arterial hypermyotrophy or other arterial disease, not necessarily accompanied, as far as my observations go, by any notable alteration of the general blood pressure or of cardiac increase or diminution.

5. That senile epilepsy (convulsive attacks) is generally due to increased blood pressure with cardio-arterial hypermyotrophy.

All these attacks of senile syncope, senile vertigo, and senile epilepsy merge into and are associated one with the other; vertigo may occur at one time, convulsions at another, and the same patient may in the end die from syncope (when the heart is defeated).

The *treatment* of epileptiform and other like seizures occurring for the first time in advanced life follows naturally from the preceding remarks. Having investigated the other possible causes, the main thing is to concentrate our attention on the circulation—examine the heart, the arteries, and above all (from the point of view of treatment) the blood pressure. Then we must be guided by what we find to administer treatment to raise or lower blood pressure and to tone or to steady the heart

This patient, A. B., presents three conditions: (1) Inherent instability in the vaso-motor centres throughout life; (2) cardio-arterial hypermyotrophy; and (3) extremely high blood pressure. There may be a toxæmia. For the first bromides are useful to steady the instability, but nothing will eradicate it; for the second nothing can be done to remove the structural changes; for the third we can do much by a spare, well-regulated diet and by such remedies as the iodides, nitrites, &c., and regular purgation. The treatment of high blood pressure often falls within the province of the neurologist, and we may bear in mind that most of its known causes come under four headings: (1) *Deficient elimination* or deficient oxygenation of nitrogenous food, alcohol even in moderate doses in some, sedentary habits, and constipation; (2) various *toxæmic conditions*, such as renal disease, gout, intestinal toxins, diabetes, plumbism, &c.; (3) any condition leading to a recurrent *spasmodic contraction* of the arterioles, such as migraine; (4) plethoric conditions generally—a very good reason for bleeding, which is undoubtedly one of the promptest, most efficient methods (and, strange to say, the good effects will last a very considerable time) of relieving high blood pressure. It is nature's method. I can remember several of my old patients who remained well as long as periodic epistaxis (every six months or so) occurred, but when this ceased they incurred apoplexy and died, or became imbecile paralytics. We should do well sometimes to imitate nature's methods of dealing with her own difficulties.

---

[3] Loc. cit.

THE RÔLE OF THE PERINEAL BODY DURING LABOUR AND THE CONDUCTION OF DELIVERY IN RELATION THERETO.*

BY R. H. PARAMORE, M.D. LOND., F.R.C.S. ENG.
HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE perineal body is that collection of tissues, which is wedge-shaped on mesial sagittal section, situated between the divergent extra-pelvic part of the vagina and anal canal. It is limited below by the skin between the anterior margin of the anal orifice and the fourchette, and laterally it passes outwards towards the ischial rami and tuberosities, to lose itself in the fat of the ischio-rectal fossæ. Since it is situated below the musculature which, with the coccyx and the ano-coccygeal raphe, forms the pelvic floor, it is outside the influence of the intra-abdomino-pelvic pressure, and for this reason, and because of the paucity of its tissue contents as palpation in the living readily discloses, it is plain it can play no part in the support of the pelvic viscera, nor can it be maintained that its rupture facilitates prolapse.

It is composed of subcutaneous tissue in which are embedded superficial muscles which have evolved from the superficial layer originally surrounding the primitive cloaca and which, like that, are sphincteric in function. Thus, the most—indeed, the only—conspicuous elements found within it clinically are the anterior parts of the two sphincters of the anal canal, both of which, by passing a finger into the rectum and another into the vagina, can be easily felt and their limits defined. The scanty pre-rectal fibres of the pubo-rectalis muscle, those passing to the perineal body from each side and forming a link between its two arms of origin and upon which Piquand and Hue[1] lay so much stress, cannot even be perceived by palpation. Further evidence of its structural weakness is shown by those cases in which part of the child—e.g., its arm—is burst through its tissues to be born at the anus, or in which the child itself has traversed bodily through it. Its thinness, the occasional occurrence of its central rupture, and the partial or complete laceration of its tissues so frequently found in women in whom the pelvic viscera are efficiently retained within the pelvis, all point to its insignificance and demonstrate its incapacity to play a part in the support of the viscera; a conclusion amply confirmed by the many failures which result in the attempt to cure prolapse by its repair alone. In spite of such facts, this truth concerning the perineal body has not been sufficiently recognised. Emmet[2] in 1883 clearly showed his poor opinion of it; but in spite of the indisputable facts he brought forward, his audience ridiculed him.

During childbirth, however, the perineal body exercises a far-reaching influence on the mechanism of delivery, an influence which is neither necessary nor good. That the part it plays is not necessary is shown by the occurrence of quite normal labour in cases of its previous rupture; that it is not beneficial is the task I have taken upon myself to show.

It is universally known that the fœtal head, which passes through the pelvic cavity flexed and which impinges upon the pelvic floor in the same attitude, is extruded from the body by a movement of extension. This mechanism may be divided into two periods: (1) in which primary extension occurs, caused by the resistance of the pelvic floor; and (2) in which secondary or continued extension occurs, caused by the resistance of the perineal tissues. That is to say, the occiput rotates around the bony unyielding boundary in front, whilst the forehead and face sweep past the stretched superficies of the levator, the stretched posterior commissure of the pubo-rectalis muscle, and the stretched tissues between this and the vulvar outlet—i.e., the flattened-out anal canal and perineal body.

The fœtal head in its descent first meets the superficies of the levator (region of coccyx); indeed, it is directed downwards and backwards from above and necessarily must do so. Not only is this evident by the bulging of the tissues behind the anus, but also on palpation of this region the hard head can be felt. Descent occurs. The coccyx is caused to recede and the levator becomes deepened and transformed into a broad, gutter-like declivity, sloping downwards and forwards, in which are placed the empty and flattened-out rectum and the intra-pelvic part of the vagina with the fœtal head. This deepening and widening of the levator takes place by a lengthening of its muscle fibres—i.e., of the iliococcygei—which pass inwards and backwards from the lateral pelvic walls to the ano-coccygeal raphe. At the inferior extremity of this gutter-like formation into which the pelvic floor is converted, the displaced and stretched posterior commissure of the pubo-rectalis muscle is found.

This muscle—called the pubo-rectalis, because it passes backwards from the pubes and encircles the rectum, the arm of origin of one side becoming continuous with the arm of origin of the other behind the gut,[3] surrounds the aperture in the pelvic floor through which the urethra, vagina, and rectum pass to reach the surface of the body from the pelvic cavity. During childbirth the pelvic floor aperture is enormously distended, and the muscle which surrounds it in a sphincter-like way correspondingly stretched. It is only when this dilatation of the aperture and stretching of its muscular boundary has been begun by the advancing pole of the fœtal head that this meets with the tissues situated beyond the aperture—i.e., the tissues surrounding the extra-pelvic part of the vagina[4] and the vaginal and vulvar orifices, of which the perineal body forms the posterior and most yielding parts.

Great as is the displacement of all these tissues during childbirth (i.e., of the pelvic floor itself and of the superficial tissues situated beneath it), that of the pubo-rectalis muscle is not so marked as one would think, for the increase in length of the tissues between the tip of the coccyx and the fourchette, which occurs during parturition, is for the most part the result not merely of a displacement but also of a marked stretching of the superficial tissues—i.e., of the anal canal, perineal body, overlying skin, extra-pelvic part of vagina, and superficial muscles (ext. sphincter); but whilst probably the raphe of the pelvic floor itself (ano-coccygeal raphe) stretches to some slight extent the chief change in this is limited to its displacement. This is shown by the position of the anus and by the anatomical fact that the posterior commissure of the pubo-rectalis is above and behind it. At the acme of birth the inferior margin of this muscle posteriorly is on the average about five inches distant from the fourchette. One has but to recall the enormous stretching of all these parts, the dilatation of the anus measuring as much as an inch or an inch and a half, and the extraordinary increase in length of the antero-posterior base of the perineal body measuring three inches or more (i.e., from the anterior margin of the dilated anal orifice to the intact fourchette) to realise how much all these superficial tissues beyond the pelvic floor extend and how thin they become. If we allow the distance from the inferior margin of the pubo-rectalis muscle to the posterior margin of the anal orifice to measure another inch, and it can scarcely be less than this, the five inches are accounted for. A comparison of the increase in the length of the tissue between the tip of the coccyx and the posterior margin of the anus with that in those between the same limit of the anus and the fourchette demonstrates how much greater is the stretching in the latter than in the former, the increase of which is largely due to the alteration in direction which the anal canal undergoes.

This stretching of the superficial tissues occurs, not only antero-posteriorly, but also transversely, and is accompanied by considerable tension. This tension demonstrates that they are offering a considerable resistance to the onward progress of the fœtal head. The tension in the transverse direction signifies a closer pressure upwards and forwards of the fœtal head against the pubic arch; whilst the tension antero-posteriorly determines its more forward and even upward projection, or rather of its anterior segment, for the fœtal head has now become converted into a relatively long ovoid. *Owing to the stretching of the perineal tissues in* the antero-posterior direction, the plane of the vulvar aperture becomes extremely oblique and approaches the coronal plane. That is to say, it looks considerably forwards. But the plane of the *pelvic floor* aperture is not nearly so oblique; it is, in fact, not far removed from the horizontal plane (i.e., in the erect posture); it still looks much more downwards than forwards—the location of its posterior commissure above and behind the anal orifice demonstrates this. Thus whilst the posterior extremities of the planes of these two apertures are considerably distant from one another, their anterior extremities are in close approximation. Since these apertures, although superimposed, are not in planes parallel with each other, it follows that an ovoid body passing through them at the same time must, whilst it is passing through one with its long axis perpendicular to the plane of that aperture, pass obliquely through the other. As the head reaches the pelvic floor aperture, bounded laterally and posteriorly by the pubo-rectalis muscle, it *begins to dilate it by endeavouring to pass through it* with its long axis at right angles to the plane of the aperture, for the resistance of the aperture causes the smallest circumference to distend it. When, however, the anterior extremity of the *fœtal head* has extended beyond this aperture it impinges upon the perineal body, and in its endeavour to maintain its direction and to continue with its long axis in the same straight line it forces the tissues of the perineal body downwards, which [illegible] in front of it, and in virtue of [illegible] ed posteriorly to its head within the birth canal and presents with it, it is easy to understand how it can be forced through the apex of the perineal body into the rectum, for it is only separated from this passage by the posterior vaginal and anterior rectal walls and the intervening connective tissue. It does not burst asunder the fibres of the pelvic floor musculature, but it passes through the pelvic floor aperture in a quite regular manner, and only deviates from one passage (vagina) to the other (rectum), both of which leave the pelvis by passing through the same aperture in the pelvic floor. And if in an ordinary vertex presentation with the arms in their usual position, the head is forced straight onwards against the perineal *tissues, and these are not able to deflect it forwards,* because it may be they yield too easily, not only do they stretch but, provided the uterine contractions are sufficiently strong, they also rupture, the child passing through the *breach, leaving the fourchette and vaginal orifice* perhaps intact. In this case, too, the transit through the pelvic floor is regular, and it is an error to suppose that its musculature is injured because of this event.

---

[2] Study of the Ætiology of Perineal Laceration, Transactions of the American Gynæcological Society, vol. viii., p. 195, 1883.

[3] The part of the muscle behind the gut is the "posterior commissure." This is not to be confused with the "posterior commissure" of the vaginal orifice, which is placed below the pelvic floor.

[4] The extra-pelvic part of the vagina is that part situated between the pelvic floor aperture and the vaginal orifice (situation of hymen). Normally, it measures about a half to three-quarters of an inch in length. During childbirth, its posterior wall, which is closely incorporated with the tissues of the perineal body, becomes markedly lengthened as well as stretched from side to side.

Usually, however, in spite of considerable stretching of the tissues of the perineal body, and because of their position, their tension, and the resistance they offer to its progress, the extension of the head which is begun by the pelvic floor itself is continued, as can be seen in primiparæ. That is to say, the advancing pole of the head is deflected. This is easily accomplished, for owing to the length of the fœtal head a comparatively slight force will cause the direction of its long axis to change. So that, if the head enters the vulvar aperture, now considerably removed from its former position, with its long axis at right angles, this [illegible] changed [illegible] e passing at right angles through the plane of the pelvic floor aperture, but that it shall have become oblique. That is to say, that the pubo-rectalis muscle, instead of embracing a circle of the fœtal head, finds itself applied to an ellipse, the circumference of which is considerably greater than that of a circle, and therefore the muscle is correspondingly increased in length and subjected to a correspondingly increased stretching. If, however, the vulvar aperture is destroyed by a laceration, the movement forwards of the anterior extremity of the fœtal head does not occur, an oblique diameter does not occupy the pelvic floor aperture, and this, therefore, escapes a greater distension.

That the intact and unimpaired perineal body is, in fact, instrumental, by causing this increased distension of the pelvic floor aperture during childbirth, in effecting those [illegible] prolapse has its possibilities [illegible] is shown by the fact that [illegible] that, whilst the perineum has not been torn, there is marked evidence of its having *been considerably stretched*, such as can only be accounted for by the part it plays in causing secondary extension of the head. These cases have been explained by supposing that a subcutaneous or sub-mucous laceration has occurred: an untenable hypothesis in view of the fact that when these tissues as well as the skin and mucous membrane have been lacerated a prolapse by no means necessarily results, for it is quite common to see a lacerated perineum, so far from being subsequently complicated by a prolapse, to be quite free from visceral extrusion. Nor can these cases be explained by supposing some change or increased intensity of action of the intra-abdomino-pelvic pressure, the determinant of prolapse, has occurred. There is no doubt that the perineal body does play a part in childbirth to the detriment of the pubo-rectalis muscle; and that a laceration of its tissues by permitting birth with the least possible *distension of the* pelvic floor aperture may undoubtedly in some or in many cases prevent that injurious elongation or possible rupture of the muscle fibres (pubo-rectalis), which, limiting the aperture *laterally and posteriorly, cannot when injured so efficiently* guard it, and thus disposes to this dystrophy.

It is not to be thought that the perineal body exerts always a baneful influence, because all it can do is to determine an increased *distension of the pelvic floor aperture; that is not* necessarily an increased injury to the pubo-rectalis muscle, although this implies a greater elongation of its fibres; and as a factor in causing impairment of the muscle it is to be regarded in the same light as the size of the fœtal head. When this is small and remains more or less spherical during birth its continued extension will not cause an increased stretching of the muscle; when, however, the head is large and is moulded to the ovoid shape by its transit through the bony pelvis the slightest degree of this secondary extension will determine an increased stretching which may "precipitate" a laceration of the muscle fibres, or if this has already occurred may cause a greater injury.

Nor does the fact that in some cases a prolapse is found subsequently to co-exist with a perineal laceration negative the view here put forward. Rupture of the muscle fibres does not alone depend upon the elongation to which they are exposed; they are living tissues, and it is the manner in which they react to this lengthening which determines their *laceration. This again depends upon the time in which they* are allowed to stretch and is more likely to occur when the stretching is sudden (precipitate labour) than when it is gradual. It also depends on their condition of tone and their *resistance to this stretching, conditions* determined by the general health and the straining. Other conditions being equal, it is certain the greater the stretching the more probable the injury, and, the fœtal head being normal (i.e., ovoid in shape) and its size remaining *constant*, it is also certain that the stretching of the pubo-rectalis muscle will be the greater when secondary extension of the head occurs during birth, least when this extension is prevented as much as possible.

But such cases may be explained in another way. It is well known that tears of the perineal body often begin in the recto-vaginal septum; and it is easy to understand how deflection of the anterior pole of the head forwards towards the symphysis will determine an increased stretching of the vaginal tissues, just as it does to the pubo-rectalis muscle situated at the same level, and that if an injury is to occur as a result of this stretching it will do so posteriorly, where the movement of the fœtal parts is greatest. This extension of the head, then, may not only cause an injury to the pubo-rectalis muscle, but simultaneously a laceration of the perineal tissues. But when the perineal tear begins at the fourchette and passes backwards and upwards, it is caused in a different manner (by direct pressure of the advancing fœtal pole, not of a posterior part of the head, and instrumental delivery), and with a different result, for this allows secondary extension to diminish, or prevents its occurrence.

If during delivery these perineal injuries are prevented, or endeavour is made to prevent them, either by opposing the advance of the fœtal head, and thus allowing time for sufficient stretching, or by actually supporting the perineum, no good is achieved other than a preservation of these tissues; but much harm may accrue to the pubo-rectalis muscle from such manœuvres. And it would seem that an early perineal tear, and one beginning at the fourchette, in the place of being a disaster is often a blessing in disguise. Yet much is done nowadays to prevent perineal tears, and one institution vies with another in the hope of obtaining the smallest percentage of these trifling injuries. Further, so much insistence is laid on the immediate and accurate suture when laceration does occur that it is impossible but to think the advocates of these measures consider the perineal body subserves important functions in connexion with the visceral support. Perineal tears should be regarded in the light of superficial wounds elsewhere and treated in the same way. When the external sphincter of the anal canal is ruptured this indeed calls for repair; but when the laceration is "incomplete" there are only two reasons why it should be sutured: (1) to check hæmorrhage, and (2) to prevent infection of the wound and subsequently of the vagina. The question of "cosmetic effect" can scarcely influence us. To lay the emphasis that is laid on the repair of these tissues from the point of view of subsequent visceral support is surely to mislead, for we know that prolapse frequently does not occur even when the rupture is complete. Thus Matthews Duncan stated that a knife could be passed into the anus and brought out at the vulva and all the tissues divided between with no resulting prolapse. He based his statement on the experiment Nature so frequently performs for us, and pointed to the not uncommon cases of complete tear of the perineum without prolapse. He indeed thought that the cause of this non-descent was because the viscera were maintained in position by a suction upwards (i.e., atmospheric pressure), but we know now that the reason of this postural maintenance is caused by the continued activity of the pelvic floor musculature, which passing *behind* the anal canal remains intact in spite of such an incision.

If, then, the facts we have recited are true, and clinically we know them to be true, the question arises, What is the best method to adopt during delivery? It is obvious that attempts should be made to prevent secondary extension of the head. This is best done by the method described by Toff,[5] who advocated it as a means of perineal protection. When the anterior extremity of the head has appeared at the vulva and begins to distend it, two or more fingers should be placed between it and the symphysis pubis and traction exerted backwards. This should be especially done during the pains. It will be found that the natural tendency on the part of the head to extend can be easily overcome. Simultaneously, pressure may be applied above and behind the anus and is exerted upon the upper pole of the fœtal head, not only tending to maintain the attitude of diminished extension but also actively assisting the expulsion of the head. It may be thought that such a manœuvre will inevitably result in a tear of the perineal skin and other tissues. Strange to say, it does not do so; indeed, it frequently prevents such an accident, for it allows birth to occur with the least possible distension of the vulvar outlet.

I have practised this method of delivery on several occasions, and it has come to form part of my routine in these cases. It is simply wonderful how rapidly delivery can often be effected in this way and what real help it is to the patient.

Gordon-square, W.C.

A CASE OF ENDOTHELIOMA MYXOMATODES OF THE MAXILLARY ANTRUM.

By HERBERT TILLEY, B.S. Lond., F.R.C.S. Eng.,
SURGEON, EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

(*With a Pathological Note by* S. G. Shattock, F.R.C.S. Eng., *Pathological Curator, Royal College of Surgeons of England.*)

The clinical features of the case which forms the subject of this communication were so interesting and the pathological findings so extremely rare that they deserve being placed on record. With reference to the last point I am sure that no similar case has been recorded in any English journal, neither can I find any references to the disease in those standard French and German text-books devoted to diseases of the nose and its accessory cavities. On the other hand, I am quite convinced that in the month of October, 1907, I operated upon a precisely similar condition in so far as the patient's symptoms and the appearances and physical characteristics of the growth could be relied upon to establish the identity of the two cases. A histological examination of the tissue was made in this earlier case, but the report was so fragmentary that it would scarcely justify me at this juncture in recording more than the one and later example of endothelioma myxomatodes of the antrum.

History of case.—The patient, a married woman, was sent to me by her medical attendant on April 16th, 1909, complaining of "stuffiness of the left side of the nose with a slight mucopurulent discharge from the corresponding nostril and heavy colds in the head." These symptoms had been especially noticeable for the past four months. In a letter describing her symptoms in more detail the patient says: "For several years I have had bad headaches sometimes and always when tired, becoming more severe towards evening and lately most severe at night when they would awake me. I generally found a mustard plaster at the back of my neck and behind my left ear would give relief. My so-called headache affected the whole left side of my face, I had toothache, earache, and *severe* pain in my left eye. During a severe attack I could give my mind to nothing and sometimes felt something peculiar about the sight of my left eye, a sort of mistiness, and on about two occasions I seemed to see only about half an object; for example, in looking at the time I would only see three-quarters of the face of the clock."

On examination the left antrum was dark on transillumination, but neither in the canine fossa, over the left side of the hard palate, nor within the nasal cavity were there any very definite signs of distension of the antral cavity. Only in the left middle meatus and corresponding to the upper membranous portion of the inner antral wall I noticed a distinct fulness which offered slight resistance to the probe and gave much the same impression as would be derived from probing soft beeswax. I pierced this region and inserted a small spoon such as is used in aural work and withdrew upon it a very thick reddish-brown gummy substance such as I had only once before seen in this region, and this was in the earlier case already referred to. There were no polypi in the left nasal fossa, and beyond slight con gestion in the middle meatal region and the fulness of it outer wall (*vide supra*) these regions presented no abnor mality. The inner antral wall was now punctured by passing a Lichtwitz's trocar and cannula upwards, outwards, and backwards on the outer aspect of the inferior turbinal bone On injecting warm boracic lotion a sense of resistance wa felt, no fluid returned through the nostril, the patient experi enced a sense of fulness in the cheek bone and the secon upper left bicuspid, which was filled with an amalgam stopping, commenced to ache. Concluding that som unusual condition was present in the antrum I advised thorough examination under general anæsthesia, and obtaine the patient's consent to do what seemed best in any circum stances which might arise.

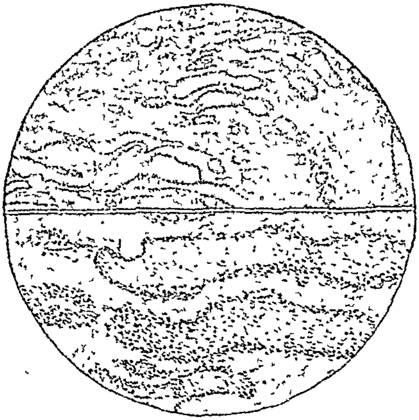
Under chloroform anæsthesia the left posterior naris wa plugged with a small captive sponge, the anterior two-third of the inferior turbinal removed, and the canine fossa full exposed through an incision in the gingivo-labial fol extending from the malar ridge to the canine root. Th antrum was now opened through the canine fossa, a hole o the size of a sixpence being made. The sinus was seen to b fully occupied by a growth the surface of which was of bluish-grey colour. There was no hæmorrhage from its surface nor was there any purulent or muco-purulent dis charge in the antrum. On removing some of the growth with a ring curette it was found to consist of a semi-solid, reddish-brown, gummy substance—in fact, I can think of no better simile than that the antrum appeared to be filled with a huge raisin in which the "stones" were missing. It was quite easy to remove this substance, which could almost be shelled out, and the lining of antrum appeared to be little altered from its natural condition. A little general oozing of blood occurred and it was impossible to find any region from which the growth seemed to take its origin. The inner antral wall and the anterior ethmoidal cells were next removed through the opening in the canine fossa, the parts cleansed, and the bucco-antral wound sutured.

The patient left the nursing home at the end of a week, and has recently written to me saying: "The operation has greatly relieved the symptoms, I have no stuffiness now, and have only had one headache at all the same nature since then; it was not severe, but my left ear ached a little, and I had [illegible] time."

---

[5] Einige Worte über den Dammschutz, Münchener Medicinische Wochenschrift, vol. lv., p. 524, March, 1907.

[illegible] physical characteristics of the [illegible] were so unusual that I forwarded it to Mr. S. G. Shattock who subjected it to an exhaustive examination and has furnished me with the appended detailed report. Under his direction Mr. Ford (38, Berners-street, W.) has made the accompanying drawing which illustrates a typical portion of the growth under high and low powers of the microscope.



[illegible]). [illegible] nd [illegible] he [illegible] as [illegible] he

It would be interesting to know if such a condition has been met with by other surgeons, for I am convinced that my earlier case (October, 1907) was of the same nature. The patient's symptoms were almost identical except that her headaches were so constant and severe that her general health had been severely undermined and she looked so worn out and cachectic that one would not have been surprised to have discovered some advanced malignant disease or grave constitutional disorder.

The naked-eye appearances and the very sticky nature of the growth were identical in the two cases. In the first I obtained the following report from the pathologist: "The matrix of this tissue is composed of fibrous tissue which has undergone hyaline and granular degeneration. In the interstices of this necrobiotic tissue are seen scraps of infiltrated mucous membrane and bits of comparatively healthy fibrous tissue in which the nuclei of the individual fibres can still be seen."

The first patient has remained free from recurrence for two years and is now in perfect health, a consummation devoutly to be wished for in my second and more recent case.

PATHOLOGICAL REPORT BY MR. S. G. SHATTOCK.

The material consisted (in addition to two pieces of mucous membrane) of three somewhat voluminous masses, the largest about 2·5 centimetres in chief diameter and 1 centimetre in thickness, of soft mucinoid material, which rapidly swelled when immersed in water. It could be divided by the lightest pressure; the semi-transparent surface of the section so made was speckled with a more opaque, whitish substance, but presented no fibrous or other recognisable structure. The addition of acetic acid to a smear on a slide rendered it opaque from coagulation, the coagulum not dissolving in excess of the acid. The material readily hardened in formol and allowed of perfectly satisfactory study by means of frozen sections.

The sections were cut vertically to the free surface, and were stained, some with Ehrlich's hæmatoxylin; others with this followed by eosin; with carbol-thionine; and with Scharlach. The sections display groups of cells parted by an abundant mucinoid stroma, and often taking the form of long, slightly tortuous columns. The cells composing the groups are closely packed, and their nuclei of very diverse forms, distorted and flattened as though pressed out of shape by the swelling of the intervening stroma. There are no polymorphonuclear leucocytes or lymphocytes amongst or around them. The cytoplasm is distinctly visible in isolated cells, and in the carbol-thionine preparations stains slightly differently from the stroma. The cells are quite distinct from the other substance and take no part in its formation.

The general irregularity of form and the grouping of the cells, *together with the manner in which the groups become* attenuated and lost in the stroma (single, isolated cells of the same kind occurring in sparse numbers in the latter), recall the histological picture of certain types of endothelioma. There is nowhere any lumen to the groups. None of the "cancer bodies" present in carcinomata were found in any of the cells. The sections stained with Scharlach show that not a few of the cells contain moderate numbers of minute droplets of fat.

The stroma is everywhere in excessive bulk, and is either homogeneous or presents marks of fibrillation, with very few or no pertaining corpuscles. The substance in question has, it is clear, arisen from mucinoid degeneration, swelling and coalescence of the connective tissue fibres of a stroma between the cell groups; even where the fibrillation is most pronounced the individual fibres want the normal aspect and take an abnormal stain. In the preparations treated with hæmatoxylin the material is of different shades of violet, and so differs from normal fibre, which remains uncoloured. In the carbol-thionine preparations the material stains of a pale violet and pink, the two merging one into another; here and there it is traversed by a certain number of long twisted ribbon-like processes of a bright red colour, which from the way in which they follow all the windings of the circumjacent substance are evidently of the same kind, although the difference in colouration marks some slight difference in chemical composition.

A noteworthy feature in the degenerate stroma is the presence of long coarse crystals, tapering at the ends, and occurring singly or in bundles. In the carbol-thionine preparations these are stained of a pale sky blue; in the hæmatoxylin and eosin preparations they are of a pale orange; in the hæmatoxylin alone, they are uncoloured. That they are not due to the action of the reagents used is evident from the fact that in the material examined in the recent state the same crystals were present. In the microscopic sections, the crystals when cut transversely are regularly hexagonal, and this is equally true of those that are isolated and not subject to the lateral pressure due to their grouping. As to their nature, I have been unable to obtain information. They appear to be in some way connected with the degenerative process, and are described here rather for any future interest they may have than for any present.

The growth itself may be classified as an endothelioma of which the stroma has undergone mucinoid degeneration. An analogous condition is met with, though it is rare, in carcinomata. One such example only has come under my own observation. This was a carcinoma of the breast; the groups of epithelial cells retained their usual disposition, but the stroma was represented by a mucinoid material, staining violet in hæmatoxylin preparations, and arising from degeneration of the fibres of the stroma; the cells between the altered fibre persisted, some of them being branched, and so rendering the tissue mucous in character, although the mucinoid intercellular material arose from the degeneration and disappearance of the fibre. No crystals were present in the stroma. Such a change may be viewed indifferently as a mucinoid degeneration of connective tissue or as a metaplasia of common connective tissue into that known as mucous.

The term "Carcinoma myxomatodes" has already been applied to carcinomata of which the stroma consists of mucous tissue, and the same adjective may be used to cover the condition present in the tumour under consideration. The *growth would be an Endothelioma myxomatodes.* In the common endothelioma of the parotid gland the endothelial groups of cells lie partly in an open tissue of branching cells, but elsewhere in a hyaline matrix furnished with similar branching cells, the two stromata being transformed one into another. But the gross physical characters of such tumours are not myxomatous or myxoma-like; they are not comparable to the endothelioma described in the present report, and they would not merit the same name.

THE FATE OF DAMAGED JOINTS:

A STUDY OF CASES OF INJURY, PRINCIPALLY FRACTURES, *INVOLVING JOINTS TREATED IN THE MASSAGE* DEPARTMENT OF THE LONDON HOSPITAL.

By RICHARD WARREN, M.D., M.Ch. Oxon., F.R.C.S. Eng.,

ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL; *FORMERLY SURGICAL REGISTRAR TO THE* LONDON HOSPITAL.

Although belonging to the commonplace, injuries in the neighbourhood of, and directly or in course of treatment involving, joints provide a theme of no small interest both to the practitioner and to the patient. To the former they furnish a field for diagnosis, prognosis, and diversity of treatment; while to the latter the ultimate result is the all-important consideration. It is with the last point of view chiefly in mind that the material for the following paper has been collected, but in judging of result it has been attempted to ascertain what has been the influence of treatment for good or evil. Moreover, in these latter days, with the overcrowding which is becoming more acute, with the liability of employers for the compensation claims of their injured workmen, with the increasing struggle for existence of individuals, and with the constant, though often unseen, wrestling for supremacy with other nations, a knowledge of the ultimate fate of accident cases, of what use they are as citizens and breadwinners, and the reasons why they recover with greater or less rapidity is of more than common interest. It is of small value to know that a patient left hospital with "first intention scar," or "firm union, no shortening." Inquiry must be made about the later fate of such a patient, whether he can earn his living and in general behave as a normal citizen should do, *some months or years after* treatment has ceased. A knowledge of the ultimate condition of injuries and fractures and the length of time necessary for full recovery is the foundation of a sound prognosis, so necessary in compensation cases. Owing to the rapidity with which patients of the hospital class change their place of abode they are not always easy to trace, but of about 400 cases rather more than one-third have been seen or have sent reports of themselves from one to two years after the original injury, and of others there are notes of the progress after several months.

The views here set forward are based on a study of cases personally seen and supervised in the massage department of the London Hospital for the last two and a half years; the figures given are taken from a continuous series of nearly 400 cases taken for a period of about 18 months during that time. My thanks are due to the surgical staff of the London Hospital, under whom these cases have been previously in the wards and in the out-patient department, for their courtesy in allowing me to make use of their cases for this purpose.

Joints Considered.

There are six large joints in the limbs all of which are fairly frequently subjected to violence; of these the hip and the knee are not considered here for the following reasons. Injuries about the hip are usually found in old people, who, if the damage be sufficiently grave to be worthy of attention, are, as a rule, rapidly deported to infirmaries and are seldom seen in the out-patient department of a large hospital; consequently the numbers seen in our massage department were not enough to form any sort of series. Injuries about the knee consist chiefly of fractured patellæ and internal derangements of cartilages or synovial fringes; the main treatment is therefore operative, depending on the proper application of the Listerian method, though, nevertheless, movement and exercises play a most important part in the after-treatment. It is more fitting that the results should be described by those who have performed the operations. There remain to be considered the shoulder, elbow, wrist, and ankle. The treatment of injuries in these positions is usually by fixation of various kinds, massage, and movements, both active and passive. Interference by open operation is seldom required in these cases, though there can be no question that under certain conditions wiring, suturing, screwing, &c., of bone by the open method can be used to great advantage.

Varieties of Injuries.

The injuries coming under notice are fractures (including injuries to epiphyses) and dislocations; sprains form a small proportion of the cases treated. Of fractures those only are taken which are found within about two inches of a joint. This is, perhaps, an arbitrary line of distinction to take, because really all fractures of long bones involve the neighbouring joints, if not at the time of injury, at any rate during, and unfortunately sometimes owing to, treatment, as is shown by the number of stiff knees after fracture in the middle of the femur and stiff ankles after fracture of the middle of the tibia. In a practical survey of the results of fractures it is the joints which are to be considered, for the joints, and not the bones, are the units of function.

General Considerations regarding Fractures.

The ultimate goal to be attained in these cases is the restoration of function—i e, the limb must be able to work. It must never be forgotten that bone is not the only tissue involved in fractures, or, indeed, the most important in a considerable number of cases. Few fractures, particularly in the vicinity of joints, are perfectly simple, but all the neighbouring tissues, muscles, tendons, vessels, nerves, and joints participitate more or less in the catastrophe, and to each of these due attention must be paid. The relative importance of each component part of the limb must be respected in treatment. By regarding the limb as a whole, and by treating it as such and not merely looking after the broken bone, we shall obtain the best results most rapidly. A patient will not feel very grateful for having the bones of his limb restored to the symmetry of an Apollo Belvedere if at the same time the joints, tendons, and muscles around are affected with the same statuesque rigidity.

It is not altogether easy to define when function is properly restored; one is often surprised by the inability to perform heavy work on the part of a patient whose limb on examination appears to have complete mobility and strength. Malingering is often suspected and sometimes rightly, but the fact must not be lost to view that in many walks of life a fitness and efficiency are required such as is possessed by a trained athlete. We all are aware what a comparatively slight strain of muscle or joint will put us completely off our stroke at any game, so it is not difficult to believe that men whose business it is to climb unstable ladders, sling about hundredweight bales, or get around amongst whirling machinery may be incapacitated by small defects of which there are no signs in the consulting-room. In addition to these, cases of clear functional or hysterical disability turn up from time to time.

Fixation versus *Movement.*

In the management of fractures, particularly those near joints, two apparently opposing principles of treatment present themselves, fixation and movement. The former includes splinting, strapping, bandaging, and operation; the latter massage, passive manipulation, and active movements. The former, i.e., fixation, stands for apposition of the ends of the fragments and maintenance of good position; the latter for free circulation of blood and lymph, mobility of joints and tendons, quick return of muscular power, and, finally, more rapid union of bone, provided that movement be not of such a nature as will cause displacement and prevent union. Slight movement between the fractured ends is of not the least harm, indeed may be beneficial after the first few days; before that it may increase hæmorrhage, exudation, and clot between the ends of the fragments; but movement must on no account be enough to cause displacement of the fragments, unless in a direction to improve their position. Movement and displacement of the fragments are very different things and must be carefully distinguished. The question often arises in treatment as to whether the bone or the parts about it are the more important. This depends on the power of repair of the patient, a property which diminishes with the age of the patient and the ageing of his blood and lymph vessels. Beyond a certain age, which varies greatly in different patients, but which may roughly be put at from 40 to 50, the tendency to thrombosis, œdema, osteo-arthritis, and adhesions in joints and tendon sheaths very rapidly increases. Therefore in persons of advancing years it is necessary to look to the functions of joints, tendons, muscles, nerves, and vessels rather than to an exact return of the bone to its anatomical structure and shape. We may safely put up in plaster the joint of a child for months, and yet speedily reproduce a moveable joint, as is well seen in the treatment of tubercular joints and congenitally displaced hips; but if we fix the joints of men of 40 and upwards even for a week we run a grave risk of producing a fixity and rigidity which will take months to recover and may result in permanent disablement; all the more is this the case where the joint has been previously injured.

In the leg, again, restoration of the anatomical shape of the bones is more important than in the arm, since a shortened leg means some degree of limping. At the same time there is no doubt that more patients limp, and limp more grievously, from stiff ankles than from shortened legs. Unless the amount of shortening be gross, such as an inch or more, the effect of shortening on the gait is but trifling.

Far more important than shortening is a deficient restoration of the axis of the limb, or allowing the fragments to form a kink; owing to this, the strain of the body weight, &c., is not applied in the proper direction, and such conditions as flat-foot, knock-knee, and bow-leg arise.

Fixity of the ends of fragments does not tend to make them unite, often the contrary results, as the efforts to keep them still with splints, strapping, &c., cause their nutrition to be so impaired from deficient blood and lymph supply that union is slow; whereas in cases of delayed union repair is found to be greatly accelerated by the more vigorous sorts of massage—e.g., deep kneading (*vétrissage*), hacking, and clapping—in the course of which slight movement of the ends of the fragments is inevitable.

The use of splints, strapping, bandages, wires, bolts, and bars, is to produce apposition of the fragments and not rigid fixation, which is unnecessary. In cases where good apposition of the fragments cannot be attained without undue pressure from splints, bandages, &c., it is best to have recourse to open operation and the various methods of bone suture, screwing, &c., as is well shown by the good results of fractured patella, spinal fractures, and so forth. Except in certain situations, however, open operation is seldom necessary. Taking now the special regions involved:—

The Ankle.

Under this heading are classed sprained ankle, fractured lower end of the fibula, Pott's and Dupuytren's fracture, fractured internal malleolus, and separated epiphyses. There is a class of case closely allied to this group to which brief allusion may be made—viz., cases of stiff ankle with foot-drop and contracted tendo Achillis following on fractures of the tibia and fibula in their middle and lower third. These cases result from failure to keep the foot at right angles, or, in other words, from a slipping up of the heel, with the leg put up on the L-shaped back and side splints. This is an important reason for taking down and inspecting these fractures frequently, moving the ankle-joint and seeing that the foot remains in proper position. This trouble is, I am sorry to say, not uncommon, and is the chief source of disability in fractures of the tibia and fibula.

Of cases more immediately involving the ankle, the commonest group attending our department consists of Pott's fractures—i.e., a fracture of the lower part of the fibula with dislocation of the ankle, associated with fracture of the external malleolus or rupture of the external lateral ligament. The injury is usually due to a *wrenching of the foot outwards, rarely by a wrenching* inwards; of 37 cases only three showed inward displacement. In practice one sees every grade of damage caused by eversion of the foot, which may be arranged in the following order: 1. Fractured fibula about three inches from the lower end. 2. Stretching and tearing of the external lateral ligament, a form of sprained ankle, liable to end in flat-foot. 3. Fractured internal malleolus. 4. A combination of 1 and 2 or 1 and 3—*i.e.*, fractured fibula with dislocation of the ankle or Pott's fracture. 5. The same as 4, but with marked displacement of the foot backwards due to rupture of the anterior and posterior ligaments of the ankle-joint, with displacement of the anterior tendons and rupture of their tendon sheaths. This is a severer variety of Pott's fracture. 6. Dupuytren's fracture in which in addition to the damage of 4 or 5, the lower end of the fibula is torn from its attachment to the tibia with great widening of the ankle. Of these, the last is quite rare, fracture of the internal malleolus alone not very common; the others are everyday cases. My impression is that rupture of the internal lateral ligament in Pott's fracture is more commonly found than fracture of the internal malleolus, though the latter condition is fairly common.

It is stated that Pott's fractures are frequently compound. I have not found this to be the case; only one case of compound fracture occurs in the present series, and this is in accord with my experience of a large number of Pott's fractures seen at the London and Poplar Hospitals. Compound fractures of the tibia, about the middle, are far more common. Perhaps the present infrequency of compound fractures of the ankle is the result of the teaching of more enlightened first aid to the public, for one sees a good many fractures about the ankle which are nearly compound and which, with rough or bungling manipulation, might easily become so. The condition (5)—i.e., Pott's fracture, with marked backward displacement of the foot—is not common; it does not occur in *more than one or two cases out of ten Pott's fractures.* The ligaments and tendon sheaths torn in this condition I have ascertained from some experiments with cadavers. It is fortunate that this backward displacement is uncommon, for when present it is apt to be overlooked, especially when there is much swelling of the ankle—a condition, again, likely to obtain owing to the greater violence necessary to produce the rupture of ligaments in consequence of which the displacement occurs. In such a case it is often extremely difficult to make out the position of the foot with regard to the ankle; it is only by realising how much the heel normally projects backwards that it is possible to estimate backward displacement and by comparing with the sound side. X rays will, of course, make the matter clear, but they cannot always be obtained. With practice the eye is the best guide, and excessive projection backwards of the heel can be recognised at once, and it is most necessary so to do, for if not corrected there will be later greatly impaired dorsiflexion of the foot—i.e., partial equinus—with all the accompanying disability from bent-kneed progression, shortened stride, and limping.

As to results, the following classes have been made: (*a*) Very good, when the patient can walk any distance and do a hard day's work—e.g., as engine-driver, carman, stevedore, &c.—whether the ankle appears anatomically perfect or not. As a matter of fact, few of the cases showed no signs of the fracture afterwards. (*b*) Good, when the patient can walk and work well, but with a slight limp of weakness. (*c*) Fair, when the patient can walk but tires early. (*d*) Bad, when the patient can only limp a few hundred yards.

Pott's fracture.—Of recent Pott's fracture 34 came under observation *and treatment; of these, two were lost sight of* too soon to be of any value. Put in a tabular form, with the number of months after injury the cases were followed, the results are:—

	Seen after				
	2-3 months.	4-6 months.	6-9 months.	18-24 months.	Total.
Very good ...	—	1	—	7	= 8
Good	6	3	1	3	= 13
Fair	5	4	—	1	= 10
Bad	—	—	—	1	= 1

That is to say, two-thirds of the cases terminated favourably and were good working results. Of the cases labelled "fair," some probably later would, if it were possible to trace them, be found to be good, as is shown by the small number of cases called "fair" amongst those seen after a considerable time. On the other hand, some of those which appeared fair results after two to three months may have degenerated later into "bad." Three cases of Pott's fracture with inversion of the foot occurred in the series; all did well. Five cases of Pott's fracture of old standing came under notice. Of these, one of two years' standing improved in five months but was not a good result; the patient was unable to do a full day's work. A [illegible] accident [illegible] at the en[illegible] soon to be of any value.

Length of treatment.—The length of time these cases remained under treatment was c[illegible] varying from three to seven months [illegible] rage time being three to three and a half months. The results, however, in the cases where treatment was prolonged were good.

The following conditions were found to increase the length of treatment necessary: 1. Œdema of the ankle and leg, which occurred to a marked degree in five of the cases where treatment was of long duration, and is one of the most troublesome things in fractures about the ankle; it is, no doubt, due to thrombosis of veins and lymphatics of varying extent, and its frequent occurrence and great persistence is a plea for early massage in these cases. 2. Long splinting, a probable cause in three cases. 3. Severity of the original injury, in one case a Dupuytren's fracture and in another very bad backward displacement of the foot, both of which imply a greater degree of violence and consequent damage to soft parts with a correspondingly longer period of convalescence. 4. Compound fracture. 5. Debility, in a patient who died a few months later from phthisis. The case which ended quite badly was rather old (60 years) and developed bad osteo-arthritis of the ankle and flat-foot. Similar changes to a less extent developed in some of the cases of which the termination was fair.

Fractured fibula.—Of fracture of the lower end of the fibula 17 cases were treated, of which one was lost sight of too early to be of value; tabulated, as in the case of Pott's fractures, the results are as follows:—

Seen after	2-3 months	4-6 months	12-24 months		Total
Very good	1	—	6	=	7
Good	2	4	—	=	6
Fair	1	2	—	=	3

The length of treatment varied from five to 12 weeks, the average length being six weeks. As might be expected, the results are better and the treatment shorter here than in Pott's fractures. In the cases which required the longer treatment there was some damage to the internal lateral ligament, although not sufficient to constitute a Pott's fracture.

Fracture of internal malleolus.—Three cases of fracture of the internal malleolus alone occurred, and of these two were good results when seen three and 20 months later respectively; one case was not traced. The length of treatment of these cases varied from six to 12 weeks.

Sprained ankle.—Of nine cases of sprained ankle five were perfect results; four were only fair, the patients being troubled with varying degrees of flat-foot. Treatment was, as a rule, only necessary for a month or less; in a few cases several months' treatment were necessary, in one case as much as five.

Taking the results as a whole, they are very fair, but the time expended in treatment was considerable; the greater the damage to the soft parts the longer was it necessary to continue treatment. At any rate, this is a less gloomy picture than that given by some writers on this subject; one reads, for instance, that cases of Pott's fracture lose 75 per cent. of their working value, or that satisfactory recovery from Pott's fracture is almost unknown. A great deal depends on the way in which they are treated.

Treatment.—The treatment of the cases quoted here varied at the commencement according to the views of the house surgeon. As a rule, for Pott's fracture, fractured internal malleolus, and fractured fibula, splints were used for two to four weeks with or without early massage. The splints used were either the L-shaped back and side splints or the external L-shaped splint, as will be described later. In a few cases plaster bandages were applied for some weeks before massage and movement were used; it is noteworthy how much longer treatment these cases required, yet in the end with perseverance and unflinching toil the results even here were not to be despised. As a rule, after three to four weeks in splints the cases were sent out in a divided, removeable plaster (Croft's), and massage and movements instituted.

The following method we have found most serviceable in Pott's fractures, fractures of the internal malleolus, and some cases of fractures of the lower end of the fibula where there is reason to think that the internal lateral ligament has been strained, and is the method which has been in use at Poplar Hospital for some years. Bearing in mind the troubles which arise from imperfectly conducted treatment—viz., everted, splay or flat-foot and equinus, or both—the foot must be put up in a position of inversion, of dorsiflexion to a right angle, and without backward displacement. An anæsthetic may occasionally be necessary, especially in the variety with displacement backward. The splint which best answers this purpose is the L-shaped external splint with a foot-piece, known to us as a Sharpe's splint, but described in some books as a Roughton; the latter in our nomenclature consists of a Sharpe's splint with a small projecting back-piece behind the heel to prevent backward displacement of the foot. We find a small separate splint about eight inches long equally efficacious in preventing this displacement. The following are the points in applying the splint. 1. A good pad should be placed under the outer side of the foot between the latter and the splint and below the external malleolus; this pad inverts the foot and at the same time protects the internal malleolus from pressure. 2. The knee must be very acutely flexed; as a rule in pictures of this sort of splint the knee is represented as only slightly flexed. To act properly the thigh should be flexed on the belly and the leg on the thigh, thus relaxing as far as possible the tendo Achillis and greatly obviating any tendency to drawing back the foot and plantar flexion of the ankle. 3. The bandage is arranged as follows: it is pinned to the hinder edge of the splint before the leg is placed in position behind the ankle; it is then brought forward under the ankle between the latter and the splint and back again over the ankle and the small, separate posterior splint and so round the whole splint and down over the foot and foot-piece. This arrangement pulls the tibia back and pushes the heel forward and usually suffices to keep the foot in good position. Should this plan fail, it will be better to have recourse to tenotomy of the tendo Achillis to relax its pull on the heel rather than use strapping.

No doubt good position can in many cases be attained with the ordinary L-shaped back and side splints, but only if there is no backward displacement; moreover, with back and side splints there is a greater tendency for the heel to slip up, producing equinus, and there is nothing to produce inversion of the foot. Another great benefit of this splint is that massage may be used early without displacing the limb or the splint. Having now got the foot in good or even over-corrected position the rest of the treatment consists of massage followed in turn by passive and finally active movement. Massage may commence as early as the third day, dependent on the liability to displacement and the skill of the masseur. If there is any doubt on the latter point the surgeon had better see to the massage and movement himself, or if time does not permit of this wait a week or ten days before allowing the masseur to perform; this will mean somewhat longer treatment. A skilled masseur should, however, know when the fracture is in good position and how to counteract any tendency to displacement, and if he can deal with the case from the start treatment will be shortened. For the first few days he will confine himself to stroking upward (*effleurage*) the foot, ankle, and calf to remove blood clot and exudate from the tissues, and will move the toes without removing the limb from the splint, an easy matter on a Sharpe's splint; after from seven to ten days gentle movement of the ankle may be instituted, taking care that the direction is such as corrects deformity—viz., dorsiflexion and inversion of the foot, at the same time the calf muscles may be more vigorously massaged (*pétrissage*). After three weeks the foot may be placed in good position in a divided plaster and treated with massage and movements as an out-patient. The patient should be able, as a rule, to put the foot to the ground in six weeks, but old people and bad fractures, with much bruising and œdema, must not put weight on the foot for much longer. Each case must be judged on its merits. Placing weight on the foot too early will certainly lead to flat foot; it is better to wait too long than not long enough. For a week or two before the foot is placed on the ground active exercises can be practised; these consist of flexion and extension of the ankle and toes, together with a rotary inversion of the foot. When the foot is placed to the ground the same exercises are continued, the patient rising on the toes and heels alternately, with gradually increasing weight on the foot. At this juncture it is important to attend to the gait of the patient; most patients of the hospital class walk naturally with the foot splayed out to some degree; after an injury to the ankle this fault is exaggerated, especially if the dorsiflexion of the foot be impaired.

We must teach them to walk with the toes pointing straight forward, and to help with this a very good exercise consists of walking with the toes turned in as far as possible, taking very short steps, a favourite exercise for flat-foot cases. With such exercises a well-set case will soon walk well and powerfully. Unfortunately, many cases came under notice two or three weeks after the accident in which the position is not all that could be desired; there is outward displacement, outward splaying, and impaired dorsiflexion, separate or combined, and in varying degrees. Here the treatment is similar but prolonged, much passive movement in the direction of dorsiflexion and inversion being necessary. Still more important are the active movements of the same nature.

In some rebellious cases skipping was adopted with moderate success, but it was found that, although useful in some cases of early flat-foot, yet in these cases of fracture the slower movements, such as rising on the toes and heels, were more beneficial, and that if a patient could skip he was, as a rule, able to follow his ordinary avocation.

The treatment of the other injuries about the ankle should be conducted on the same lines, but as a rule the foot can be placed to the ground much earlier. Where there is certainly no displacement no splint is required; when in doubt it is best to splint in the manner described, because the troubles of ankle cases are always in relation to the conditions of splay-foot and equinus.

A type of sprained ankle is sometimes met with which may be regarded as a potential Pott's fracture—i.e., although the fibula is unbroken yet the internal lateral ligament is damaged to such an extent that it will stretch if weight be placed on the foot too early, causing flat-foot. Similarly in cases of fractured fibula the same structure may be so damaged that, although there is no displacement at first, it will give way when walking is commenced, having then the typical appearance of a badly set Pott's fracture. Great care is necessary to avoid falling into this trap. The question of instrumental support may arise and if adopted should be used early; cases which are not in the best position would doubtless be improved by a walking instrument double to the knee with a valgus strap and possibly a toe-raising spring. In cases which are not progressing favourably the timely expenditure of two or three guineas early might well save the continuous drain of charity doles in later days.

(To be continued.)

PULMONARY TUBERCULOSIS TREATED BY DEEP MUSCULAR INJECTION OF MERCURIC SUCCINIMIDE.

By J. EDWARD SQUIRE, C.B., M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST;

AND

J. A. KILPATRICK, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE SENIOR RESIDENT MEDICAL OFFICER AT THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE employment of mercurial preparations for the treatment of consumptives is no new departure. When one of us (J. E. S.) received his first appointment as assistant physician to the Mount Vernon Hospital 25 years ago all the patients of his predecessor in the out-patient department were treated with mercury, usually in the form of the perchloride. In more recent years the treatment of pulmonary tuberculosis with mercury has been given up, the success obtained being hardly sufficient to counteract the disadvantages attending a prolonged course of mercury administered by the mouth.

A medical officer of the United States Navy (Surgeon Barton Lisle Wright[1]), having observed that the administration of mercury to syphilitics with tuberculosis of the lungs resulted in a marked improvement in the pulmonary lesion, employed this remedy in cases of consumption in non-syphilitic individuals with results which were decidedly encouraging. He administered the mercury by deep muscular injections of "tabloid" hypodermic mercury succinimide (gr. 1-5th) and found that both the local and the general conditions materially improved. Messrs. Burroughs and Wellcome kindly placed at our disposal a supply of these tabloids for the purpose of a further trial, the main objects in view being to see if the favourable report of the former trials were corroborated and to determine if possible how long treatment must be continued in order to effect a cure. It should be noted that in all cases the administration of the drug is ancillary to the hygienic or sanatorium treatment, and that it is not possible to decide to what extent any improvement observed may be attributed to the effects of the injections. Nevertheless, in certain of our cases which had been for some time under treatment before the mercury injections were commenced improvement was certainly more marked and more rapid when the mercury was given than it had previously been. Though we have experienced none of the startling results reported from America the results of the injections are sufficiently encouraging to justify further and more extended trials with this remedy. We are, however, unable to give any decided answer to the second subject of inquiry, as to the length of time the treatment must be continued in order to effect a cure, if cure can be brought about. Our trial of the remedy has extended over a period of four months and it would be at least premature to say that any of the cases are cured. We selected for trial cases in various stages of the disease in the lung and a few cases in which there was tuberculosis in the larynx or other parts as well as in the lungs.

The method of treatment recommended by Dr. Wright is as follows:—

"[illegible] *de gr. 1-5 No. 98 is the* [illegible] m. of sterile water, con- [illegible] at another place.

The treatment is started with one injection gr. 1-5 every other day [illegible] by a two weeks' [illegible] iodide gr. 5, two [illegible] lrice daily. Then one week's rest from medication, after which the injections are resumed, and so on.

This treatment was undertaken in 14 cases but after two injections one case had to be abandoned. After the first injection the patient complained of such violent pain down the leg that one was almost led to believe that the sheath of the sciatic nerve had been penetrated, but on a subsequent occasion the other buttock was merely pricked with an ordinary sterile needle when the patient complained of the same violent pain. No further treatment was attempted in his case.

Of the 13 patients who were treated some for various reasons—wishing to return to work, domestic trouble, having to undergo a surgical operation, &c.—were not able to remain as long in hospital as one could have wished in order to give it a fair trial. The buttock was chosen as the most convenient place for injection, and, of course, every precaution was taken to sterilise both the needle and the part injected. For each injection 1-5th grain was dissolved in 10 minims of distilled water; this was injected into alternate buttock every second day, Sunday being excluded. In the case of the females no injection was given during the menstrual period. In all cases careful attention was paid to the teeth and a mouth-wash was used after each meal.

While none of the patients objected to the form of treatment it cannot be said that any of them liked it. With few exceptions there was always a brawny lump, varying from the size of the tip of one's little finger to the size of one's thumb or a little larger at the seat of injection for about 48 hours. On one occasion a lump arose in about half an hour almost the size of one's closed fist; the same evening it was about half that size, and next morning it had almost disappeared.

All the patients complained of a slight burning or pricking pain at the seat of injection for a time, varying from 6 to 12 hours. This was more noticeable when the injections were first commenced, and later the patients complained less of it. Three of the patients felt faint after the injection on three or four occasions and one of them had a slight vomiting attack immediately after. The female patients complained less of the pain than the males. This

* Lung trouble. Hip-joint disease three years old. Knee-joint disease five years. Leg amputated then.

the fact that nature has provided them with more adipose tissue in that region and therefore sitting down would cause less discomfort.

The patients treated—six females and seven males—varied in age from 15 to 51 years; all, with one exception, were more or less advanced cases, three having cavities and all had tubercle bacilli in the sputum.

In one case it was noticed that the sputum was swarming with bacilli on the first examination. About ten days later they were decreased by half, and in another week one had to look carefully for them, there were so few. In another case, though the physical signs decreased the bacilli increased. In most of the remaining cases the bacilli decreased, and in one case none could be found after a couple of weeks' treatment.

A remarkable fact which applied to most of the cases was the rapidity with which the physical signs decreased. This continued for the first four or five weeks. Then, with two exceptions, most of the patients arrived at a stage where no further change could be made out, and some of them even returned to their former condition. In two cases the physical signs disappeared altogether.

THE SEWERAGE OF BUDE (CORNWALL).—The Bude sewerage works, which have been erected at a cost of £14,000, were formally opened on July 1st by Mr. A. C. Thynne, in the presence of a large gathering.

LITERARY INTELLIGENCE.—Mr. H. K. Lewis has purchased the remainder of the stock of the New Sydenham Society's publications, comprising the collection of volumes on medicine and surgery, the "Pathological Atlas," the "Lexicon of Medical Terms," and the "Atlas of Clinical Medicine, Surgery, and Pathology," issued by the society during the years 1859–1907. Many of the works were of a pioneer character when issued by the society and have since acquired a historic importance. The number of copies of each book has been of necessity limited on account of the heavy expense of warehousing a larger stock, and of many of the volumes only a small number remained over.

NOTES ON THE USE OF X RAYS IN THE TREATMENT OF MALIGNANT DISEASE.

BY C. E. IREDELL, M.D. LOND., M.R.C.P. LOND.,
SURGEON IN CHARGE OF THE ACTINO-THERAPEUTIC DEPARTMENT OF GUY'S HOSPITAL.

THOUGH the X ray treatment of rodent ulcer is now so successful that it will probably become the routine method of dealing with that disease, it is less generally recognised that in other forms of malignant disease X rays have in some cases a certain definite value.

During 12 months beginning in March, 1907, 31 cases of malignant disease, excluding rodent ulcer, have been treated with the X rays at Guy's Hospital. These cases are here recorded with a view to showing the uses of this form of treatment. Of these cases 23 were inoperable, the remaining eight having been sent immediately after operation for X ray treatment in order to prevent recurrence. The effect of treatment most frequently observed in the inoperable cases was the relief of pain. In 13 cases this relief was well marked, and it extended over weeks or months, and where tenderness was present this also subsided at the same time. The pain, which was variously described as "pricking and shooting" or "dull and aching," was relieved in all three forms of malignant disease, the relief being more complete but of shorter duration in the more rapidly growing tumours. Except for this difference, growths which were dissimilar microscopically seemed to respond to treatment in the same way. After a single treatment to a tumour in which there is pain it becomes easier within 24 hours and remains so for a few days, the ler[illegible] X rays given. It [illegible] and gradually re[illegible] so severe as to keep the patient awake at night sleep becomes possible after treatment.

The relief of pain is followed by the diminution in size, and in some cases the disappearance, of the tumours. Malignant glands in the neck and axilla, subcutaneous nodules in the skin, and in one case a secondary deposit in the sternum two inches in diameter cleared up. In malignant ulcers the relief of pain is followed by a diminution of the discharge; if offensive, it loses its foul smell, and finally the ulcer may heal. Ulceration was present in seven cases and in six some improvement was obtained. Figs. 1 and 2 show the improvement in Case 2 at an interval of two months, and two months later the patient was almost well. Unfortunately no photograph was taken then, and while away on a holiday death from lobar pneumonia occurred.

In Case 10 there were two large fungating masses on the inner aspects of the buttocks, and there was a discharge which was so offensive that it was necessary to burn fumigating pastilles in the ward while the patient was being treated. After a few weeks of treatment the discharge became much less and lost all its offensiveness, and the fungations became smaller and cleaner. In Case 28 the discharge was so offensive that it was noticeable to anyone entering the room in which the patient was while the dressings were still on, and so profuse that though thick dressings were changed four times a day it always soaked through to her clothes. It soon lost its offensiveness and became less, and at the present time the ulcer has to be dressed only twice a day.

The local improvement is associated with an improvement in the general health of the patient, as shown by the fact that the appetite improves and that patients look and feel better. This improvement may be due to the relief of pain, the increased amount of sleep, the drying up of an offensive discharge, or the mental impression produced on the patient by the use of the complicated apparatus with the noise and sparking which are unavoidable in X ray work. Though one or more of these factors may be sufficient to account for the general improvement in some cases, in others they seem inadequate. In this connexion Cases 15 and 18 are of special interest. In both there were cachexia, loss of appetite, and daily vomiting. No ulceration was present and pain was absent in Case 18. After the first treatment the vomiting

ceased, and the change in appearance was so noticeable that both patients said that their friends had remarked upon it. Both became worse on going to the seaside and improved again when treatment was recommenced. Subsequently the tumours became too numerous for treatment and the patients went down-hill. A possible explanation is that malignant cells produce an internal secretion which is inhibited by X rays, that this secretion circulating through the body produces a cachexia, and that it is finally excreted into the stomach, there producing a distaste for food and in some cases vomiting.

The use of X rays in influencing the occurrence of secondary deposits is shown in Cases 17 and 3. In Case 17 (see Fig. 6) the shortness of the history, the enlargement of the glands above the clavicle, the age of the patient, and the microscopical appearance of the tumour all point to a very malignant form of new growth. The areas X rayed immediately after operation were those in which it was thought most probable that secondary deposits would occur—viz., the scar, axilla, the supra-clavicular region, and the epigastric angle. Tumours which were tender and in which shooting pain was present appeared some weeks later under the centre of the clavicle and in the inner ends of the first, second, and third ribs—i.e., in those parts of the front of the right side of the chest which had not been X rayed. One treatment was then given to the painful places and the pain was relieved. It was then thought that the tumours were not sufficiently definite to justify the conclusion that they were cancerous and the treatment of these swellings was omitted. After a time the pain returned and the tumours increased to such a size as to make it clear that they were malignant in nature. They were then X rayed regularly and completely, and they disappeared in a few weeks. In Case 3 (see Figs. 3, 4, and 5) there was a large swelling in the sternum secondary to a growth of the breast which had been removed six years previously, and when first seen no enlarged glands could be felt in either supra-clavicular or axillary regions. The only place X rayed was the swelling itself. A fortnight later enlarged glands were felt above the left clavicle, there was pain in this region as well as down the left arm, and attacks of difficulty in breathing which resembled asthma were experienced. This part was X rayed and a fortnight later there was no pain above the clavicle or in the left arm and the attacks of dyspnœa had stopped. Some months later large glands were felt above the right clavicle; these, like the glands on the left side of the neck and the tumour in the sternum, cleared up under X rays. About five months after the treatment was started the patient became free from pain and said that she felt perfectly well and this state of well-being continued for about three months, when she began to go down-hill. Small nodules of growth appeared in the lower part of the sternum, at the inner end of the left clavicle, and near the lower border of the left pectoralis major, that is each nodule appeared near the line dividing two different areas of treatment. This probably was due to the fact that the rays at the edge of a four-inch square are less intense than they are at the centre. The amount of X rays given was sufficient to prevent the occurrence of secondary deposits in the centre of the areas, but not at the edges. If this explanation is correct better results might be expected if the separate areas treated are reduced in size. These two cases seem to make it advisable to X ray, not only those places in which secondary deposits are likely to occur, but also the parts between them and the primary growth. In the case of cancer of the breast it is advisable to X ray the whole of the front of the chest, the neck, and the axillæ. Probably the lives of most of the patients in whom improvement has been noticed have been prolonged for some months, but so far nothing further can be claimed. As all the patients treated have been out-patients it has not been possible to ascertain the cause of death with certainty in those cases in which it has occurred. Some of the cases were so advanced as to be almost hopeless from the first, and in these death was probably due to internal deposits which could not be affected by treatment. In others the early signs of dermatitis prevented sufficient treatment to be given to completely arrest the progress of the growth. A dermatitis when it has subsided leaves behind it an irritable condition of the skin to X rays which lasts for a considerable time.

The irritable condition just mentioned and the period of its duration vary with the degree of dermatitis produced, and therefore the earliest signs are of considerable importance. The first thing to be noticed is a slight bronzing of the skin, which gradually becomes darker. The pigmented parts of the body become bronzed more easily than do those that are not pigmented, and bronzing comes on more quickly in those patients who are dark-complexioned and in those who are advanced in life. From this it follows that bronzing in a person of fair complexion is a more definite indication for leaving off treatment than it is in others. The second stage is a red flush which supervenes on the bronzed area. If larger amounts of X rays are given the intermediate stage of bronzing does not occur. In the third stage the redness increases and the area becomes painful, the pain varying in intensity from being slight and transient to being severe enough to prevent sleep. It is described as burning and smarting, and in the more severe degrees cutaneous hyperæsthesia is present. The patients when questioned say that the pain is quite different in character from that of the cancer, which they describe as being "pricking and darting." This distinction is important when a patient who has been under treatment for some time complains of pain. In the one case it is an indication for leaving off the X rays, while in the other it shows that X rays are not being given in sufficient quantity to check the growth of the cancer. In the next stage the pain increases, blebs form, and a raw surface with a serous discharge is left. This stage was reached in four cases. In all of them the patients were well a month after the onset of the pain; no scarring of the skin followed and treatment was resumed as before, smaller amounts of X rays being given. In these cases the sequence of events was as follows: (1) relief of the cancer pain; (2) onset of the pain due to the action of X rays on the skin (here the treatment was left off); (3) onset of cancer pain which became worse; while (4) the pain from the X rays gradually subsided.

If the amount of X rays that can be given, after a condition of irritability has been set up, is insufficient to stop the growth of the disease, its progress is retarded, and if ulceration is present the discharge is diminished. In Case 8 the patient, who was being treated for 10 minutes once a week, at first improved considerably. Redness and tingling were set up after some months of treatment and since then it has only been possible to X ray in smaller amounts, with the result that the disease has increased.

The risk of a dermatitis may be diminished, while the effect on the tumour is scarcely altered, by reducing the amount of X rays given at one treatment and repeating it more frequently. Probably if the patient in Case 8, who could come for treatment only one day a week, had come twice a week and had had half the original treatment each time, the effect on the growth would have been the same, and no irritability of the skin would have been set up. In this way the original improvement might have continued.

No really satisfactory method of estimating the quantity of X rays in small amounts has been devised yet. Fairly satisfactory results have been obtained by keeping the following three factors constant: (1) the alternative spark gap of the X ray tube at three inches; (2) the distance of the anode from the skin at seven and a half inches; and (3) the current in the secondary circuit at three-tenths of a milliampère. The length of time of the treatment is varied and is with each patient a matter of experiment. In Case 28 five minutes' exposure twice a week produced in two months smarting and redness, with three minutes' exposure twice a week the pricking of the cancer returned, while under an exposure of four minutes twice a week the patient is doing fairly fell.

Since all forms of malignant cells seem especially susceptible to the action of X rays it is not surprising that the remaining form of embryonic cell found in the body is also destroyed by X rays, as shown by the several instances of X ray workers who have become sterile. The cells from which the spermatozoa are formed are not embryonic, and it might be expected that the sterility would not be permanent. Evidence on this point is not easily obtained, but Laquerrière has published a case of transitory azoospermia. In this case there is evidence, both microscopical and otherwise, of five years' sterility in an X ray worker, followed by recovery after four months' efficient protection from X rays.

Conclusions.—1. In superficial forms of malignant disease X rays may temporarily arrest the course of the disease, relieve the pain, diminish the discharge, and heal up the ulcers. 2. Probably X rays prevent the occurrence of superficial secondary deposits. 3. Embryonic cells are more easily destroyed by X rays than are normal cells.

* Still attending for treatment when article was written.

Remarks upon the Respective Cases.

No improvement.

Case 7.—No improvement. Nodules in the scar and in the skin around it

Case 8.—Discharge and pain diminished. Ulcer decreased in size Redness and tingling produced, and since then the ulcer has increased in size

with profuse
sleep at night
tite improved
leep at night
se ground in

nodules The
ved. Pain in
s cleared up

Gained three pounds in weight. Gave up attending as she could not

ness and smarting produced by X rays to several areas and vesication in the axilla. At the present time the chest is free from recurrence. Since December there has been pain down the left leg and also œdema. No cause can be found for it, but it is probably similar in nature to the œdema found in the arm in cancer of the breast. Pain in the chest was always relieved.

Case 18.—Vomiting daily. This stopped when treatment was started. There was no pain, but the patient said that she felt better for treat-

missed

lcer has almost healed. The patient has had redness and smarting from X rays. The growth in the breast itself is larger than when treatment was started.

Case 20.—Arm swollen and œdematous (not improved). The shooting pain in the scar yielded to treatment, as also did the enlarged glands in the right supra-clavicular triangle. The pigskin condition of the left breast has cleared up.

so diminished as to make sleep possible. Redness and tingling from X rays produced.

Case 29.—No improvement noticed.

Case 30.—Prophylactic.

Case 31.—Prophylactic.

Devonshire street, W.

A CASE OF SEVERE FACIAL CARBUNCLE, WITH LUDWIG'S ANGINA AND PAROTITIS,

SUCCESSFULLY TREATED BY VACCINES, COMBINED WITH THE ADMINISTRATION OF REPEATED DOSES OF CITRIC ACID.

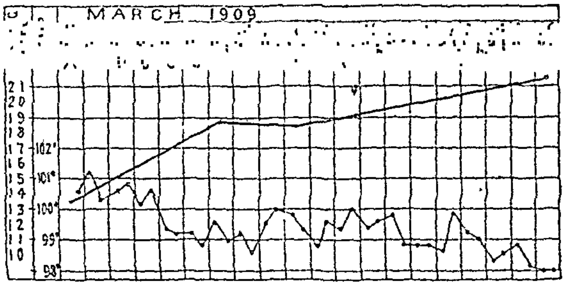
BY H. B. WALTERS, M.R.C.S. ENG., L.R.C.P. LOND.;
RUSSELL COOMBE, M.A. CANTAB., F.R.C.S. ENG.,
SURGEON TO THE EXETER DISPENSARY;
AND
R. V. SOLLY, M.D. LOND., F.R.C.S. ENG.,
PATHOLOGIST TO THE ROYAL DEVON AND EXETER HOSPITAL.

THE patient whose case is now described was a girl, aged 17 years, under the care of Mr. H. B. Walters at Chudleigh. On Feb. 22nd she noticed a pimple on the right cheek, which she squeezed, but no pus exuded. When first seen two days later she had a hard indurated inflammatory mass of about the size of a shilling on the right cheek, adjoining the lip. The temperature was 99° F. Fomentations and a mixture containing perchloride of iron were ordered. On the 27th the upper lip on the right side began to swell, and on the following day pus was discharging by many small holes from its under surface and the lower lip was beginning to swell. The temperature was 101°. On March 1st the symptoms were in every way worse. The local conditions were as follows. The whole of the right cheek was dusky in colour, with an indurated swelling extending upwards from the lip, the eye being nearly closed and the groove on the side of the nose nearly obliterated. She was almost unable to open her mouth, there were sordes on the teeth, and the tongue was very foul. There was no fluctuation present. The temperature was 103°, the pulse-rate was 140, and the patient was in a drowsy, semi-delirious condition and evidently very ill. Mr. Russell Coombe having been called into consultation, Dr. R. V. Solly was sent for with a view to vaccine treatment and he immediately inoculated a dose of 50,000,000 staphylococci (mixed stock vaccine). On the 2nd there was not much change, but the patient's temperature was rather lower and there was some improvement in her general condition. On the 3rd a culture taken from the pustules of the lip gave a pure growth of staphylococcus aureus, from which a vaccine was prepared, and on the evening of the above date a dose of 25,000,000 staphylococci was administered. On the 6th it could be seen that definite improvement had taken place since the last injection. There were less swelling of the upper lip and less discharge, but there was a good deal of submaxillary swelling of a brawny character, suggesting Ludwig's angina. Another injection of 25,000,000 of the patient's own staphylococci was given. On the 7th it was found that blood withdrawn into a Wright's blood capsule, with a view to estimating the opsonic index, clotted almost immediately, and therefore one-drachm doses of citric acid were administered every four hours for four doses. The opsonic index was 1·35. On the 8th the temperature dropped to 99·6° and altogether had a lower range. The patient still improved, and the swelling was gradually decreasing, the right cheek being practically well, but there being a hard indurated swelling in the left cheek. On the 9th one drachm of citric acid was administered for two doses. On the 10th, 11th, and 12th half a drachm of citric acid was administered for 12 doses. After this the temperature became gradually lower in range and the local condition improved. The opsonic index on the 13th was 1·89. On the 15th the left parotid gland became enlarged and painful. Glycerine and belladonna fomentations were applied and 50,000,000 of the patient's own staphylococci were injected on the 16th. The effect of this was to cause some malaise, but on the next morning the temperature was lower. On the 17th half-drachm doses of citric acid were again administered every four hours and were continued for two days. The temperature now gradually fell, the parotid swelling slowly disappeared, and the patient made an uninterrupted recovery, the only sign of the illness that was left being a dimple in the left cheek caused by the skin becoming attached to the mucous membrane of the cheek, just over the opening of Stenson's duct. The opsonic index on the 26th was 2·2, the pulse-rate was 76, and the temperature was 98°.

Remarks by Mr. RUSSELL COOMBE.—This is the fourth case of facial carbuncle that I have seen. The first occurred when I was a dresser under Mr. T. Pickering Pick at St. George's Hospital, the second when I was house surgeon to Mr. Timothy Holmes in the same hospital, and the third was a case I saw in private practice in North Devon some 10 years ago. These patients all died in spite of every effort. The present case is the first one that I have seen since the advent of vaccine treatment, and the result leaves me in no doubt as to the line of treatment which should henceforth be adopted in these serious illnesses. Great credit is due to Mr. Walters for so early recognising the gravity of a distinctly rare condition, and there is no doubt that without this early recognition the girl's life could not have been saved.

Remarks by Dr. SOLLY.—I think there can be little doubt, taking into consideration the bad prognosis in these cases when treated by ordinary methods and the very serious condition of this patient when vaccine treatment was begun, that this treatment turned the scale in her favour, although, unfortunately, owing to the fact that I was summoned to the patient's home at Chudleigh in a great hurry and had only time to collect material for the inoculation, no opsonic index was taken at the beginning of this treatment. All the symptoms, including high temperature, quick pulse, drowsiness, and delirium, pointed to the condition being one of extreme toxæmia and a marked negative phase. There was some improvement after the injection of 50,000,000 of mixed stock vaccine, but this was more marked after the patient had received two doses of 25,000,000 of a vaccine made from her own staphylococcus. The opsonic index, when first taken 24 hours after inoculation, was raised to 1·35, and finally, when the patient was nearly well, it reached 2·2, and the accompanying chart shows well what has been so often demonstrated—namely, that the index rises with lowered temperature, improved clinical condition, and satisfactory immunisation of the patient.

A very important point in the treatment was the administration of citric acid. At the time when this was begun there were brawny patches in the cheek and submaxillary region and the blood drawn into the Wright's blood capsule clotted almost at once. The benefit of this treatment was very soon observed, the temperature falling more rapidly, and the swelling subsiding without suppuration in the case of the left cheek, submaxillary region and parotid gland, though there can be no doubt that these parts were infected with staphylococci. Obviously the citric acid so lowered the coagulability of the blood that lymph containing large amounts of antibacterial and antitryptic bodies was freely admitted to the infected parts and the organisms were thereby destroyed before formation of pus or destruction of tissue could take place.



A, One drachm citric acid every four hours for four doses. B, One drachm citric acid, two doses. C, Half drachm citric acid every four hours. D, Left parotitis began. E, Inoculation of autogenous vaccine, 50 million bacteria. The upper line denotes the opsonic index, the lower the temperature.

We are indebted to Sir A. E. Wright for our knowledge of the means by which we may influence the coagulability of the blood by either citric acid or lactate of calcium, and he himself has reported a case of Ludwig's angina of the face where on incision no bleeding or exudation took place, and the blood withdrawn from a vein at the bend of the elbow clotted almost immediately. The opsonic index was high, and on culture staphylococci were obtained. Administration of one-drachm doses of citric acid every three hours for six doses caused rapid improvement, and finally complete recovery. I have also observed the benefit of this treatment in a case of severe carbuncle at the back of the neck and of a whitlow due to staphylococcus aureus. After the second injection of 25,000,000 of autogenous vaccine on March 6th, no injection was given for ten days as the opsonic index was raised and the condition was satisfactory. Then parotitis on the left side began and the temperature became somewhat higher in range, and it was thought advisable to give another injection. This produced slight toxic symptoms, but the temperature was lower on the next day. Citric acid was again recommenced, and after this there was never any occasion for further inoculation as the patient made an uninterrupted recovery and without any ill effects locally. Fomentations were applied as already mentioned and pus was washed away from the inner surface of the lip, but no treatment was employed other than that described and no incisions were made.

A CASE OF RETINAL DETACHMENT IN PREGNANCY ASSOCIATED WITH NEPHRITIS.

BY THOMAS WILSON, M.D. LOND., F.R.C.S. ENG.,
OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM;
AND
ROBERT BEATSON HIRD, M.D. BIRM., M.R.C.S. ENG.,
LATE RESIDENT SURGICAL OFFICER AT THE BIRMINGHAM AND MIDLAND EYE HOSPITAL.

DETACHMENT of the retina as a consequence of albuminuria in pregnancy is rare. A case resulting in complete recovery was published in THE LANCET of May 18th, 1901, by Mr. R. G. Hann and Mr. R. Lawford Knaggs, who give references to a case of detachment occurring during severe eclamptic attacks in the eighth month of pregnancy and to one of gradual onset occurring in association with general dropsy about the time of delivery recorded by Dr. Reginald Southey in a clinical lecture on Pregnancy Nephritis.

In 1902 Heilbron[1] was able to collect 21 more or less fully recorded cases, and he found that detachment usually affects both retinæ, [illegible] nied by notable diminution c [illegible] sion. In every case the deta [illegible] after delivery, but in only a small number of cases (three in 21) was the recovery of vision complete in both eyes. In one patient complete blindness persisted. The permanent diminution in vision was due not to the detachment itself but to complication by albuminuric retinitis. The retinal detachment especially affects the lower half of the eyeball and is due to exudation between the retina and choroid.

In the following case the blindness did not come on suddenly but had been gradually increasing for about a fortnight. Induction of premature labour was followed by steady improvement in vision and disappearance of general œdema, and by more gradual improvement in the renal condition.

The patient, aged 25 years, presented herself on Sept. 24th, 1907, at the out-patient department of Mr. Henry Eales, honorary surgeon to the Birmingham and Midland Eye Hospital, to whom we are indebted for permission to publish most of the observations on the condition of the eyes. The patient, who was in the eighth month of her pregnancy, complained of blurred vision and swelling of the eyelids, which had been noticed for 14 days, and had begun a little earlier on the right side. Morning vomiting had continued during the whole of the pregnancy, the ankles had been swollen for six weeks, and the urine was said to have been diminished in quantity for the last three months. There was no history of scarlet fever or of kidney trouble, no sign of syphilis, and the woman had always been strong and healthy. There was œdema of the eyelids and of the conjunctivæ. Vision in both eyes was 6/60, and could not be improved by glasses; there was some hypermetropic astigmatism. On either side the field of vision was diminished, especially above the horizontal meridian, and there was a large retinal detachment occupying the lower part of the vitreous chamber. The ophthalmoscope showed no signs of retinitis or hæmorrhages, and the optic discs were normal. The accompanying charts show the extent of detachment when the patient was first seen.

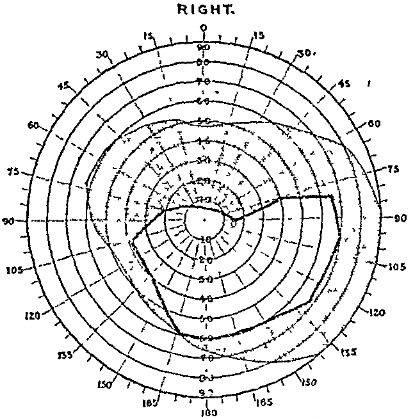


Chart showing extent of detachment.

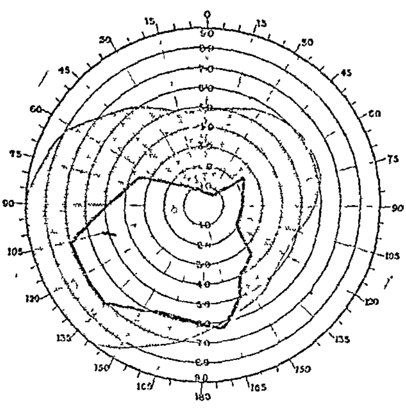

Chart showing extent of detachment.

The urine was nearly solid with albumin. The gravity of the case was at once recognised; the detached retina was regarded as part of the general œdema, and the only hope of saving the woman's sight appeared to lie in immediate treatment. The patient was therefore transferred at once to the General Hospital, where she was admitted under the care of one of us (T. W.). The account of the case that follows is taken from the notes of Dr. Charlotte Bailey.

On admission there was œdema of the face, legs, and abdominal wall. The urine was acid, of specific gravity 1030, becoming practically solid on testing for albumin. Under the microscope were seen some red blood corpuscles, together with hyaline and granular casts. 22 ounces, containing a urea percentage of 1·7, were passed in the 24 hours.

Induction of labour.—On the evening of Sept. 24th a celluloid bougie was passed into the uterus. On the next morning the os would admit the tip of the little finger, and another bougie was inserted at 10 o'clock; in the evening pains were occurring every ten minutes and the bougies were taken out. On the morning of the 26th the cervix was about three inches in diameter. The membranes were ruptured at 10 o'clock and a living child, weighing 3 pounds 2 ounces, was born two and a half hours later. The placenta was delivered a quarter of an hour afterwards and showed marked œdema of the cord. The child only lived one week.

In the 24 hours from Sept. 25th to 26th 22 ounces of urine containing 168 grains of urea were passed, dark-brown in colour, becoming practically solid on testing for albumin, showing hyaline casts but no blood corpuscles. On the following day the uterus was well contracted, the abdomen was still enlarged and bulged in the flanks, there was dulness in each flank and above the pubes, and well-marked ascites. There was great œdema of both legs and of the abdominal wall and of both conjunctivæ; the lungs were free. The patient complained of a little difficulty and oppression in breathing and of some headache. For the next three days there was a good deal of headache but the patient was otherwise comfortable and had good nights. She was treated by hot packs and by the administration of compound jalap powder each morning. On Sept. 30th, and again on Oct. 2nd, a leech was applied to each temple.

On Oct. 1st it was noted that the sight was gradually improving and that the patient could see much better. The general œdema was much less marked but there was still some ascites. On the 7th a varying degree of headache had persisted but there was no demonstrable ascites; the uterus had subsided into the pelvis. The conjunctival œdema had disappeared with the exception of a small patch on the outer corner of the left eye, while vision had gradually improved, so that large letters could be seen. On the 8th Mr. D. C. Lloyd Owen kindly reported that the curtain of retinæ had fallen back with but slight loss of function; there were some hæmorrhages along the course of the vessels and still small heapings up of the retinæ On the 13th it was reported that the patient had had mild delusions during the night and often began broken sentences. On the 14th she had a curious expression in the eyes and a sardonic smile; she was drowsy but easily roused, and had had some delusions during the night, thinking that her husband was sitting by her. There were rises of temperature to 100° F. on four days of the first ten of the puerperium and to 102° on the third day. From the eleventh to the fifteenth day the temperature was constantly raised from 100° to 102° and once to 103°. By the twenty-first day the temperature had settled down and remained thereafter normal. In the 24 hours after delivery 110 ounces of urine were passed.

R. B. C. = Red blood corpuscles. W. B. C. = White blood corpuscles.

The patient was transferred on Oct. 25th to the Birmingham and Midland Eye Hospital for further observation. She was then free from headache and œdema, and the sight was steadily improving. There had been considerable apparent loss of flesh since delivery. The fields of vision were much larger, especially the right one, which was nearly full. Sight had also improved. R.V. = 6/24 (1) with + 1·50 cyl. axis vert. L.V. = 6/36 (1) with + 1·50 cyl. axis vert. The retinal detachment had entirely disappeared in each eye and the fundi presented the following appearance:—

Right eye.—The optic disc was a little pale and not quite distinct, the upper and lower edges blurred, and the vessels running over the edge as if there was a little swelling. The arteries were about normal, but the veins were somewhat engorged and compressed by the arteries where they crossed. The whole eye ground was dotted over with pigment spots of varying size. There were thinning of the choroid and some whitish changes in the retina; a few white patches obscured the arteries in places, as also did some of the spots of pigment. All the changes were more pronounced at the periphery.

Left eye.—Similar except that the disc seemed a little paler. Afterwards sight gradually improved. R.V. = 6/18 part with + 1·0 cylinder axis vert. = improved. L.V. = 6/18 part with + 1·0 cylinder axis vert. = 6/12 most. Reads J. 1 at eight inches. Both fields of vision are quite full. *The fundi have hardly undergone any change*; there are no white patches over the vessels and no definite pallor of the discs. The patient gets occasional œdema of the lids but none of the legs.

The patient was seen in the out-patient room at the General Hospital on April 1st, 1908, looking well. There was no increased frequency of micturition, the urine was acid, and showed a haze of albumin, and on microscopical examination no blood cells or casts could be detected. At the end of January, 1909, she was again seen in fairly good health, but complained of occasional bad headaches. The catamenia had been regular. The urine, acid, 1014, contained no casts, but still showed a distinct haze of albumin.

A CASE OF ACUTE LUPUS ERYTHEMATOSUS.

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
CLINICAL ASSISTANT IN THE SKIN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, LONDON.

A FEMALE patient, aged 15 years, was admitted into St. Bartholomew's Hospital on March 12th, 1907, complaining of blueness and numbness of both hands and feet. She had been quite well up to December, 1906, when she first noticed her hands gradually becoming blue and numb. A few weeks later the feet likewise became affected. For some years previously the patient had suffered from chilblains. Past history and family history *nil ad rem.*

On admission the fingers and toes were bluish, showed old scars, and were cold to the touch. There were some blotchy red patches on the face. The nose and ears were normal. The urine was normal. The temperature was 97·4° F. and the pulse was 108. The patient complained of abdominal pain after food. Further examination revealed nothing. A few days after admission a red rash appeared all over the face and on both wrists, extending up the forearms, being accompanied by a persistently raised temperature. The urine was tested for hæmoglobinuria, but none was found. March 26th: The face had become very much worse, the nose appeared cyanosed, and albumin was present in the urine. April 3rd: The nose had become very sore and swollen, also the upper lip, so that the patient had to breathe entirely through the mouth; she also complained of headaches. 12th: The face, the hands, and the feet were better, but patches of erythema appeared on the arms and a papular eruption on the back, many of the papules being conglomerated together to about the size of a sixpenny-piece, and having a desquamating surface. The lungs were carefully examined and they showed nothing abnormal. There was a gallop rhythm at the heart's apex. The central nervous system was examined and the deep reflexes were found to be markedly increased. There was marked pseudoclonus and a questionable true clonus of the left ankle. The plantar reflexes on both sides were also questionably of the extensor type. Dr. H. Lewis Jones tested the electrical reactions of the arms and legs, reporting: "No changes except those of simple decrease of irritability, which is almost universal." 23rd: I saw the patient for the first time. The face was diffusely pigmented and erythematous; it was covered all over with scales, some of which came off easily, others being adherent; the latter on removal had those processes of horny tissue which fitted into small depressions on the skin, and which are typical of *lupus erythematosus. Minute areas* of scarring were found here and there. On having the hair cut short two bald patches were seen, covered with closely adherent scales, which when removed also showed the typical plugs and scarring. The hair was very thin elsewhere and the scalp was covered by minute scales, and was, like the face, diffusely pigmented and erythematous. A small papulo-squamous eruption covered the neck and chest. The fingers and toes were neither cyanotic nor swollen, but were distinctly painful when touched. The skin was tense and shiny, and scattered about were depressed scars varying in size from that of a pin's head to that of a split pea; they were white in appearance, had no erythema around, and most often did not occur in connexion with the follicles. This atrophic condition had spread up the back of the hands to about the middle, where the scarring was less marked, and when present was covered with scales and surrounded by a zone of erythema. Going over the wrists right up the forearms was a papulo-squamous eruption. As elsewhere, many of the scales on removal possessed the horny processes. 30th: The patient had signs of bronchitis and a bilateral facial herpes appeared. All this vanished in a few days and the temperature dropped to normal. May 18th: The fever reappeared and both hands became markedly cyanotic. Both the nose and the upper lip were again swollen and pus came out of the left nostril. 21st: The patient had some rigors, the temperature went up to 105°, and an impetiginous eruption had more or less affected the whole face. 25th: The *face began to clear up*, but there were several enlarged and painful glands in the neck. June 1st: A crop of minute vesicles (sudamina) appeared all over the chest and abdomen, accompanied by a rise of temperature and bilateral swelling of the neck in the region of the parotid glands. 5th: An abscess which made its appearance over the lower sacral region was opened and the pus was carefully examined [illegible] ically and by culture with [illegible] me onward until her discharg [illegible] of the general condition co [illegible] temperature would remain normal and the papulo-squamous rash would appear to fade, then suddenly the fever would recur and the rash would spread.

On Sept. 17th the patient was brought up to the hospital and on examination she gave all the signs of general peritonitis. She was operated on by Mr. L. B. Rawling, but a few days later she developed a purulent pericarditis, necessitating a second operation, which was followed on the same evening by death.

The pus from both the peritoneum and the pericardium showed and grew the pneumococcus. Unfortunately, no mention is made of the skin condition while in the surgical ward and no post-mortem examination was allowed.

During the patient's first stay in the hospital a blood examination was made. The culture was negative. Hæmoglobin, 50 per cent. (Haldane), index = 0·75; red corpuscles, 3,300,000; and white corpuscles, 7800. Differential count: polynuclears, 73·5 per cent.; lymphocytes, 23·5 per cent.; large hyaline, 2 per cent.; and eosinophiles, 1 per cent. No abnormal red cells were seen. Their shape was fairly constant and the staining was uniform.

I examined microscopically several pieces of skin which in every respect were typical of lupus erythematosus.

Remarks.—Cases of acute lupus erythematosus are rare, and the cases which end fatally are either associated with tuberculosis or with pneumonia. No history of tuberculosis was obtainable and since no post-mortem examination was made it cannot be excluded. Not a few cases have been described in association with lupus pernio or a papulonecrotic tuberculide of the hands and feet. Clinically lupus pernio came under consideration, but the absence of local swellings and glandular enlargements rather put it out of court, but it was finally negatived by the microscopical examination. There was complete absence of a granuloma with the epithelioid and giant cells which are invariably found in true cases of lupus pernio.

A point of great interest in this case is the age of the patient. It was not so many years ago that lupus erythematosus in childhood was said not to exist, but Galewsky[1] on searching the literature found 24 cases occurring between the ages of 10 and 16 years. Curiously enough, all these cases showed a strong similarity; in that the skin lesions were not so pronounced as in adults, being invariably of the erythema centrifugum type and affecting chiefly the face and the scalp and then the hands and the feet. Atrophy and scarring were but little marked. The disease also showed a strong proclivity towards females.

Whether c [illegible] puberty pla [illegible] impossible t [illegible] in females is due to a disposition to congestion of the face and blushing, as suggested by Hutchinson, must also at present remain a moot point.

Since all the fatal cases have followed either tuberculosis or pneumonia, one cannot help thinking that the disease is due to a toxin; the dominating erythema in such cases would certainly support a toxic view.

I am indebted to Dr. J. H. Drysdale for kindly allowing me to examine and publish the case.

St. Bartholomew's Hospital.

DONATIONS AND BEQUESTS.—The late Mr. C. G. Swan has bequeathed £500 to endow a cot at the Bristol Royal Hospital for Children and Women.—The Chelsea Hospital for Women has received from Lady Tate £1000 to endow a bed.—The Seaside Convalescent Hospital, Seaford, Sussex, has received a donation of £1000 from Mr. Otto Beit.—Among the latest contributions received at the Bank of England for King Edward's Hospital Fund for London is a contribution of £1500 from the Drapers' Company, being the half-yearly payment of their annual subscription of £3000.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Spectroscope for Testing Colour Perception.—New Cataract Pedigrees.—Treatment by Radium.

A MEETING of this society was held on July 9th, Mr. Priestley Smith occupying the chair.

Dr. F. W. Edridge-Green showed a Spectroscope for Testing Colour Perception. It is constructed like an ordinary spectroscope, except that there are a telescope and collimator both fixed, and in the focus of the eyepiece there are two shutters. These cover the whole of the spectrum, and by means of them the operator can isolate any portion of the spectrum in order to show the size of the patch which seems to be monochromatic to any person. He said that whereas it used to take him three days to examine a case by the old instrument, he could now examine one in half an hour, because attached to each shutter was a drum graduated in wave lengths, graduated to the fourth degree, which was very fine. That enabled the size of the patch to be determined without any calculation. The spectroscope could be used for seeing the exact termination of the spectrum and how far the ends extend.

Mr. N. Bishop Harman showed a chart illustrating some New Cataract Pedigrees. The cases illustrated the truth of Mr. Treacher Collins's contention that the cataract was a defect in the lens secretion which went to make the capsule. The patients had plaques on the back part, behind the nucleus, and including the posterior part of the lens. In one girl the cataract extended so as to include the nucleus, while in a further case it projected forward like a piece of coral through the lens, so that it seemed there was lens matter bulging through. At first he thought it was that, and that it had been needled and afterwards got hard and sclerosed.

Mr. Arnold Lawson and Dr. Mackenzie Davidson communicated a paper entitled "A Preliminary Note on the Treatment of Eye Diseases by Radium." They said the cases had been selected from the out-patient clinique of Moorfields Hospital and were chosen as instances of maladies which usually proved obstinate or only improved slowly under the ordinary forms of treatment, or else were of active virulent nature and so required drastic measures. Only 17 cases had so far been tried, but in every case the result of exposure to radium had been very encouraging. Most of the cases were corneal ulcerations, four were non-ulcerative lesions, and one was episcleritis. After one application of five minutes to the hypopyon there was distinct benefit. For instance, a man, aged 35 years, gave a history of injury to the right eye. There were a deep ulcer and a grey infiltrated area of 4 millimetres diameter, and there was a large hypopyon. 29 milligrammes of radium were applied for five minutes, and five days later the injection was subsiding and the hypopyon had disappeared. Two days after a second application of three minutes the man was discharged from the hospital, the eye being not quite white, but, for all practical purposes, well. Other cases also did very well under the treatment. In all cases the only other measures adopted were the use of boric lotion and atropine where required. Some punctate erosions were also similarly treated, and gave equally encouraging results, as also did cases of old-standing trachomatous pannus, except in one case, in which there was increased vascularity after the treatment. The dosage of radium was an important point, and the small dose of 5 milligrammes seem [illegible] did a much larger dose. In one case [illegible] days, but in the ot [illegible] Mackenzie Davidson explained that the paper was a tentative one. The radium was applied in sealed glass tubes, the glass cutting off the alpha rays, so that the beta and gamma rays only passed through to the lesion.—Mr. Ernest Clarke and Mr. F. Hewkley discussed the paper.

Mr. Priestley Smith then, in a graceful tribute, presented to Mr. Edward Nettleship the Nettleship medal for his work [illegible] paying a high [illegible] ed him to [illegible] ng.

Reviews and Notices of Books.

The Commercial Products of India. Being an Abridgment of "The Dictionary of the Economic Products of India." By Sir George Watt, C.I.E., M.B., C.M. Glasg., LL.D., formerly Professor of Botany, Calcutta University, and Reporter on Economic Products to the Government of India. London: John Murray. 1908. Pp. 1189. Price 16*s.* net.

The "Dictionary of the Economic Products of India," written by the same author and published in 1885-94, having been out of print for some time, the Government of India directed that a corrected and abridged edition should be brought out. As this work was to be limited to a single volume, it was decided that it should be confined to products of present or prospective commercial and industrial importance. A representative committee was appointed to draw up a scheme; this committee comprised Sir W. T. Thiselton-Dyer, K.C.M.G., C.I.E., F.R.S., Director of the Royal Botanic Gardens, Kew, as chairman; Mr. J. S. Gamble, C.I.E., F.R.S., Professor W. R. Dunstan, F.R.S., LL.D., Director of the Imperial Institute; Sir Thomas Holderness, K.C.S.I.; and Lieutenant-Colonel D. Prain, C.I.E., F.R.S., as members. The writing of the present volume extended from 1904 to 1907.

The work as now published forms a most elaborate and accurate record of all the material previously published on the subject, as well as official matter amassed in Government offices in India. It may be regarded as a useful digest within assigned limits of all available information concerning India, and should prove a work of reference of great practical value to those interested in the commerce and industry of that country. Compiled in the form of a dictionary, the various products of the country are easily ascertained. Turning to the portions of medical interest rather than those affecting other industries, we find that the indigenous drugs of India are legion, a fair proportion being recognised in the British Pharmacopœia, while those used by the native practitioners of the East embrace still further varieties. All the recognised and more important drugs are fully and scientifically described, and their production, the amount produced, their export and commercial value are stated in each case. In the past the European population of India had to rely almost entirely for its medicines on the drug-producing centres of the world; if through any unforeseen cause India had been cut off from the rest of the world—for instance, by war—the stock of European drugs in the country would have lasted but a short time, as owing to climate it is not only inadvisable but impossible to store large supplies, as deterioration occurs. Within the last decade, however, the Government of India has formed some half-dozen factories, and several enterprising civilian manufacturing druggists have followed suit, the result being that the country is now nearly self-supporting, and compressed drugs in tablet form are turned out with a skill that will compare very favourably with that of European firms. The production and manufacture of quinine give a good example of this, for the annual imports of this drug on behalf of the Government have been discontinued, India being now able to turn out a liberal supply of an invaluable drug at a remarkably low price. The working of the drug factories has given lucrative employment to a great number of persons, and a net annual profit has resulted to India of some £10,000—a truly creditable record. Packets of quinine, each containing seven grains, are now sold at the village post offices for a farthing a packet, and as this procedure has had the immediate effect of increasing the demand the future must of necessity witness a considerable expansion both of production and manufacture. Along with this the exports of cinchona bark from the country to the United Kingdom form a source of profit; in 1906-07 the exports reached 494,587 pounds. The expansion in the export traffic of castor oil is another episode of medical interest; the export for the shipping season of 1902-03 reached over 2,000,000 gallons, representing approximately £200,000 sterling.

The production and export trade in wheat and flour are of importance to record, though here we are without the province of medicine and dealing with a subject of pre-eminent national consequence. In 1904-05 the total export of wheat was over 43,000,000 hundredweights, nearly 29,000,000 hundredweights of which were consigned to Great Britain, or nearly a third of the amount imported from all other countries of supply to the United Kingdom. The wheat-producing power of India is entirely due to the increased canal and well irrigation accomplished by the Indian Government during recent years, and these undertakings will no doubt be greatly extended in the future.

The book is well printed, well bound, and has an exhaustive index; it should form an important addition to the library not only of all interested in the economic products of India but of all political students and workers.

Rational Immunisation in the Treatment of Pulmonary Tuberculosis and Other Diseases. Comprising a Paper read before the Royal Society of Medicine, March, 1909, by E. C. Hort, B.A., B.Sc. Paris, M.R.C.P. Edin. London: J. Bale, Sons, and Danielsson, Limited. 1909. Pp. 75. Price 3*s.* 6*d.* net.

The thesis maintained by the author in this book is that in infective disease injury is done to the cells of the body, not only or even principally by the actual toxins of the invading organisms, but by secondary products arising from breaking-down cells. He therefore holds that inoculation with bacterial vaccines is not to be relied on as a mode of treatment, but that methods must be adopted which lead to auto-inoculation—that is, to diffusion throughout the body of the products of bacterial action on its own cells. Other points raised are the untrustworthiness of the opsonic index as a measure of response to vaccines, and the advantage of a special method of recording and interpreting charts of temperature in disease. We have not space to discuss more than a few of the points which strike us, and in doing so we must premise that either from our own mental obtuseness or from some lack of lucidity of thought or expression in the writer we have found it difficult to follow the argument in many places. With regard to the general principle, it would seem that if the bacterial toxin gives rise to the secondary toxic products of cellular metabolism, then the inoculation of a bacterial vaccine will cause the appearance of these latter, and they will produce the resulting form of immunity as efficiently as if they arose from some focus of disease existing in the body. The only advantage of what is called auto-inoculation would appear to be the assurance that the toxins of the very organism which causes the disease are being employed for a stimulus, and this can be equally well done by making an ordinary vaccine from organisms isolated from the individual patient. With regard to the evidence that these secondary poisons are more important than the primary one, the only fact that we can recollect which tends to prove this hypothesis is the discovery by Sidney Martin of poisonous albumoses in diphtheria: hence at present the whole suggestion must be regarded as speculative. It is no doubt true that cells undergo autolysis by means of enzymes contained within themselves, and that these enzymes are enabled to act by reason of some toxic influence exerted from without on the cells which otherwise resist their action. The main object in treatment would then seem to be the counteraction of the original poison—i.e., the bacterial toxin.

We are quoting only one or two instances of that loose thinking or careless writing which occurs throughout the book. On p. 7 the author states that a cell damaged by toxins "can of its own accord only return to a normal state by inciting responsive reaction in the fertilising lymph that supplies it." Leaving aside the words "of its own accord," which we might be disposed to quarrel with as indicating that there is some other means besides its own vital energy by which a cell can recover its health, we do not understand what reaction a cell can excite in the lymph, a mere solution of chemical substances and not a living body itself. Again, take the following sentence: "The sign of restoration [of cellular integrity] is the exhibition of appropriate restraining bodies." Surely a sign is something which we actually observe, and it would be more accurate to say that the recovery of the normal appearance of the cell was a sign of the formation of the (in this case) purely hypothetical anti-enzymes. Further, on p. 22, we are told that "spontaneous inhibition of auto-inoculation is effected by all the methods which the economy employs in order to arrest the disease." If this be so, it would seem that in artificially inducing this auto-inoculation—the object of the author's teaching—we are exactly running counter to those very means of natural cure which it is the aim of every wise physician to encourage.

On the whole, while we must admit that Mr. Hort's suggestions are interesting and well worthy of study, we cannot feel that he has yet established his position, and we are led at times to doubt whether the views he has formed are in themselves really clearer than the obscure language in which they are formulated.

International Clinics. Edited by W. T. LONGCOPE, M.D. Philadelphia. Vol. IV., Eighteenth Series, 1908, and Vol. I., Nineteenth Series, 1909. London and Philadelphia: J. B. Lippincott Company. *Vol. IV., pp. 310;* Vol. I., pp. 309. Price £1 15*s.* net per set of four volumes.

AMONGST the many interesting articles in the fourth volume of the eighteenth series of this publication is one by Dr. A. G. Nicholls (Montreal) on Acute Dilatation of the Stomach. In discussing the morbid anatomy of this condition he mentions that, out of 120 necropsies, in 35 instances the whole or a part of the duodenum was also dilated. This fact, he says, has an important bearing on the pathogenesis. In a large proportion of cases obstruction is found at some part of the duodenum, more rarely at the pylorus. The most important single condition appears to be the constrictive force exerted by the root of the mesentery where it crosses the third portion of the duodenum. It is often difficult to determine which is the primary condition—the dilatation of the stomach or the obstruction. That obstruction may be the determining cause in some instances is certain. On the other hand, it is evident that dilatation of the stomach, whether acute or chronic, is competent to produce mesenteric obstruction or to aggravate it if it be already present. One thing, however, is certain, that a vicious circle is produced. Dilatation of the stomach favours the production of mesenteric obstruction, and mesenteric obstruction leads to dilatation of the stomach. Dr. Nicholls considers that the exact sequence of events cannot be definitely settled until more cases are reported with full and careful study of the clinical features.

Amongst other articles contributed to this volume are: The Advance of Physical Therapeutics, by Dr. J. N. Pratt (Boston); Traumatic Lesions of the Semilunar Cartilages of the Knee-joint, by Mr. A. N. McGregor (Glasgow); the Rôle of Insects in the Transmission of Disease, by Dr. M. A. Brown (Cincinnati); and the Neurasthenic Syndrome, by Dr. D. J. McCarthy.

Another noteworthy contribution to this volume is one on Mikulicz's Disease and Allied Conditions, by Dr. Campbell P. Howard (Montreal). In the literature of the latter part of the nineteenth century isolated enlargement of the lacrymal or salivary glands had been noted. Mikulicz in 1888 first described the condition which now bears his name, but since then several observers have drawn attention to the disease. Oheinisse and others claimed that the points emphasised by Mikulicz served to distinguish the condition from pseudoleukæmia and leukæmia, in either of which the same chronic painless enlargement of the lacrymal and salivary glands may occur. They claim, therefore, that the disease is a clinical entity and not a syndrome. This, however, is not the view adopted by Dr. Howard. He gives abstracts of 55 cases of "Mikulicz's disease proper," and then discusses the conditions of pseudo-leukæmia and leukæmia, and finally arrives at the following conclusions:—1. Mikulicz's disease is not a simple disease entity, but a clinical syndrome which varies very greatly in its form, etiology, and course. 2. Under this term must be accepted isolated as well as symmetrical disease of the lacrymal and salivary glands due to simple lymphomata, pseudo-leukæmia, leukæmia, tuberculosis, and syphilis. 3. A whole series of cases exists forming links in the chain from isolated lymphomata of the lacrymal or salivary glands to complete involvement of these glands with simultaneous disease of the lymphatic and hæmatopoietic apparatus.

Amongst other articles in this volume are the following: The Hospital for Advanced Cases of Tuberculosis, by Dr. L. F. Flick (Philadelphia); Occupations and so-called Rheumatic Pains, by Dr. J. J. Walsh (New York); Suppuration in Appendicitis, by Mr. E. M. Corner (London); and Absorption from the Peritoneal Cavity, by Dr. W. G. MacCallum (Baltimore).

Sanitary Law and Practice: a Handbook of Public Health. By W. ROBERTSON, M.D. Glasg., D.P.H., and CHARLES PORTER, M.D., B.Sc. Edin., M.R.C.P. Edin. Second Edition. London: The Sanitary Publishing Co., Limited. 1909. Pp. 694. Price 10*s.* 6*d.* net.

THE first edition of this work having been exhausted, the authors have availed themselves of the opportunity of bringing the book up to date; they have recast a number of sections and have added new ones—for example, those on school medical inspection and on vital statistics. The handbook in its present form more than ever impresses us as a most useful and conscientious piece of work, and this later issue should prove even more useful than its predecessor has done. So far as setting forth methods of administration to be adopted, and so far as giving a synopsis of the law relating to public health questions are concerned, nothing is left to be desired. It must be confessed, however, that the chaotic condition of existing public health legislation is forcibly brought home to the mind of the reader of this work, and it is perhaps open to question whether it is desirable that the student should concern himself with so detailed a study of differences in the public health enactments of England and Wales, London, Scotland, and Ireland, as appears by implication to be thought necessary by the authors of this handbook. The Scotchman who went to London found the inhabitants of that city speaking English, though as he remarked it was with a "southron accent"; and the differences between Scotch and English public health law are after all matters of small moment in comparison with many questions which are of far greater importance to the student. The authors of the handbook, however, explain that it is their desire "to meet the wants of those who are undergoing a course of systematic training preparatory to presenting themselves for examination." Do examination papers justify, it may be asked, so strict an adherence to the "practical," and such rigid insistence upon legal minutiæ? If they do, it is, at any rate, well to recognise the fact that it is possible for a student completely to master a *practical* handbook, such as this, and yet to know little of some of the problems which are likely to face him and to compel his attention when he comes to be a medical officer of health. For example, the question whether cow maladies (other than tuberculosis, to which disease a full share of attention is devoted) are concerned in producing infective qualities of milk; the question of the relation of polluted shell-fish to enteric fever; or, yet again, the question of spread of small-pox from hospitals. On such a subject as that last named we should have welcomed a reference to the work of Sir William Power, in order that the student might, at any rate, be afforded a chance of discovering for himself how to think, in some lucid interval when he was not required to devote all his energies to endeavouring to commit to memory what to think.

The ever more and more tangled growth of legislation is held to compel the devotion of more and more time by students to legal technicalities, but such time will be grudgingly given by those who have realised that public health literature is also deserving of study. It might be argued with some show of justice that the student who had mastered one of the classics of that literature at first hand was better equipped for the work of a medical officer of health than he who has all the Acts and By-laws at his fingers' ends. It would, of course, be impossible to boil down and present in concentrated form the works of the masters in a handbook such as this, but there is perhaps a danger that in the press and hurry of preparing for examinations the student may fail to appreciate the fact that even in public health "there be of them that have left a name behind them." If no hint is given to guide him, the embryo health officer is only too likely to form the opinion that the only names worth remembering in connexion with public health are those of inventors of particularly ingenious appliances.

But to return to sanitary law and practice, there are some excellent words of advice, evidently written as the outcome of severely practical experience, given to health officials in this handbook. There is no doubt about the soundness of the dictum that the medical officer of health would do well to exercise tact "in various ways on different occasions"—it may be safely prophesied he will, in the course of his career, find scope for such exercise. Particularly, however, the advice given to the sanitary inspector may be commended. "He should endeavour to make himself known in his district, but it should be because he is civil and kindly, not because he is overbearing and dictatorial."

High-frequency Currents. By FREDERICK FINCH STRONG, M.D., Instructor in Electro-therapeutics at Tufts College Medical School, Boston. London: Rebman, Limited. 1908. Pp. 289. 12*s.* 6*d.* net.

WHILE books on this subject have appeared from time to time, sometimes as separate volumes but often as a section or chapter of a volume devoted to medical electricity generally, it must be admitted that as a whole the literature relating to high-frequency currents has suffered from vagueness. It has not been altogether satisfactory. A perusal of this work leaves us with the impression that, while vagueness still exists, some progress has been made in the direction of a better understanding of the subject. In the first five chapters the historical and physical aspects of the matter are treated in a sufficiently complete manner, the author relating how all the phenomena and effects can be explained by the modern electron theory. Where the problem is a difficult one for the non-technical mind to grasp, free use is made of diagrams as well as the *water analogy* to make it more easy to understand. The next five chapters are devoted to a description of the various forms of apparatus in use. The different types are compared, and the author shows the advantages of each, and how it comes that no one apparatus of the ordinary kind can fulfill all requirements. There appear to be wide differences in frequency and volume of current obtained from different forms of instruments—those having a high rate of frequency are best suited for acting upon superficial and circumscribed areas, and the lower the frequency the better is it adapted for more deeply seated structures. The coils and transformers designed by the author seem to have some very good points, and he claims to have been the originator and inventor of large numbers of instruments and methods of using them. This is all quite right and proper, but we do not see the necessity for such constant reiteration of his having been first in the field, which is likely to prove tiresome to many readers, who, after all, are more concerned with the philosophy of the subject and such evidence as there may be of the practical results in treatment that may be expected.

A number of chapters follow which are devoted to the physical properties of these currents and the methods of applying them in treatment. Physiological and therapeutic action are treated in Chapters XXI. and XXII., but it is somewhat disappointing to find how little the author has to tell us as to the "why and wherefore" of things. Actual therapeutics are given in the last three chapters, and we think this part should have received more lengthy discussion than it has. In short, notwithstanding that the book is a good one, and one that anyone who is interested in the subject will find well worth careful attention, it is a fact that too much attention is given up to the purely technical side and too little to the practical value and use of the currents at our disposal. It is also the case that most of the methods of applying those currents here described involve the possession of the special coil designed and used by the writer himself.

LIBRARY TABLE.

Atlas of the External Diseases of the Eye. By Professor Dr. O. HAAB of Zürich. Authorised translation from the German. Third edition. Edited by G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology in the University of Pennsylvania, &c. With 101 coloured illustrations. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 244. Price 13*s.* net.—*Atlas and Epitome of Ophthalmoscopy.* By Professor Dr. O. HAAB of Zürich. Second American edition from the fifth German edition. Edited by G. E. DE SCHWEINITZ, M.D., Professor of Ophthalmology in the University of Pennsylvania, &c. With 152 coloured illustrations. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 94. Price 13*s.* net.—The favour which has been accorded to these books is shown by the frequency with which they have been reprinted and re-edited. They are trustworthy guides to the branches of ophthalmology with which they deal, both as regards the texts and the illustrations. The latter are as good as could possibly be expected at the remarkably low price. Professor de Schweinitz has added a plate to the ophthalmoscopy, but otherwise the lithographs are the same as in former editions. He has also added comments to the texts, and these will be found to enhance the value of the books and give them an advantage in matter as well as in language over the German editions for English-speaking readers.

Practical Points in Anæsthesia. By F. E. NEEF, M.D. New York: Surgery Publishing Co. Pp. 46. Price 60 cents.—This is a very conveniently produced little book, the instructions in which are based upon the practice of anæsthetics in vogue at the German Hospital, New York City. The methods in use are apparently confined to the drop method with a Schimmelbusch mask, and the tube method by means of catheter indiarubber tube and funnel. The preliminary use of morphia, one-half grain of the sulphate hypodermically half an hour before administration, is almost a routine measure. Anæsthesia is always induced with "anæsthol," a mixture of chloroform, ether, and ethyl chloride, or with chloroform. The author believes that respiratory embarrassment is always the result of "crowding" the anæsthetic, an Americanism that requires some explanation for English readers. He is evidently well impressed with the desirability of preserving as light a degree of anæsthesia as is compatible with the surgeon's requirements. Indeed, he includes prostatectomy amongst the operations for which only superficial anæsthesia is required after the skin incision. The book is too slight in its scope to be of much general service.

Notes from a Collector's Catalogue: with a Bibliography of English Cookery Books. By A. W. OXFORD. London: John and Edward Bumpus. 1909. Pp. 116. Price 5*s.* net.—The A. W. Oxford of the title-page is not only a clerk in holy orders and a Doctor of Medicine of the University of Oxford, but also busies himself with municipal work and educational matters. The modest little book before us shows the recreative side of his character—he is a collector, and one sentence of his book gives the clue to the whole art and science of collecting: "One tires of collections, but never of collecting." He commences his treatise with three rules as to how to collect wisely, as to which we refer our readers to the work itself, and then proceeds to recount how he promptly broke the second. The true joy of collecting for the ordinary collector with limited wealth is for him to buy the things he wants, or thinks he wants, which are within reach of his purse. Probably after a week or so he will find he does not want one at least of his recent purchases and then he can either sell it or give it away to a museum. The modest collector may in this way obtain as much pleasure as a prince of the tribe, such as Mr. George Salting, although, of course, he cannot hope to acquire such flawless specimens of art as anyone may see in that gentleman's loan collection at South Kensington. Dr. Oxford makes an admirable suggestion which we should like to see carried out, and that is that every village should have a museum, "in which such things as smock-frocks, flails, screeves, local engravings, should be preserved. If no proper building can be erected, why should not a part of the school, or even of the church, be used? The history of a village is its sacred history." This is quite true, and local "things," especially agricultural implements, have far more bearing on history and social matters than is generally supposed. It is probable that there is still an ox goad or two left in Sussex, for plough oxen were quite common 40 years ago and some still linger. The length of the goad was 16½ feet, from which the unit, the rod, pole, or perch, was taken. 40 rods made a furlong—i.e., furrow long, or the length of land an ox team could plough without a rest. Here is an explanatory piece of social life which is worth preserving. All local customs and folklore, too, may and often do throw light upon obscure subjects and prove to be foreshadowings of modern discoveries. For years before the antiseptic virtues of formaldehyde were extolled it was the custom of Somersetshire dairy farmers to scrub out the churns with a handful of nettles "to keep them sweet," and in "A True Gentlewoman's Delight," a cookery book of 1653, directions are given for laying a cream cheese on nettles, presumably to prevent it going mouldy. Mediæval churches were always used as museums, and there is no reason why our churches, in many places the pride of the country side, should not be similarly employed in modern days. Dr. Oxford discourses pleasantly about his various collections, which range from stay busks to old silver. Among his books is a collection of "Tractatus Varii de Pulicibus" and (in two volumes) the weekly report books from 1826–1830 of the Rev. W. Valentine, who was chaplain and house governor of the London Hospital. The reverend gentleman, it appears, had a by no means easy time with the cook, who was a lady of unfettered speech, and who was, according to one of the porters, "more like a tiger than a woman." Altogether Dr. Oxford may be felicitated both upon his collections and his account of them.

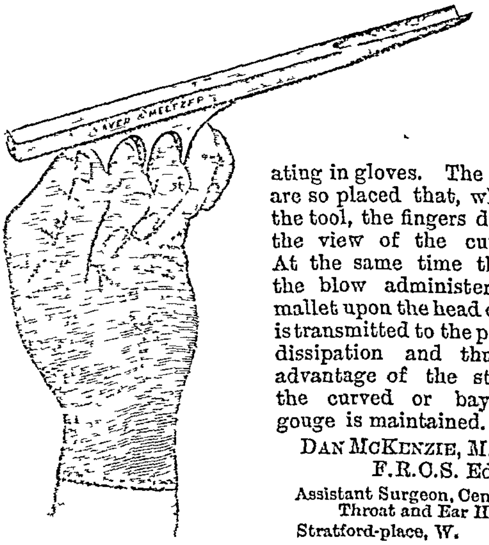
JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. II. No. 8. July, 1909. Oxford: At the Clarendon Press. Subscription price, 25*s.* per annum. Single numbers, 8*s.* 6*d.* each.—The contents of this number are: 1. Syncopal Attacks associated with Prolonged Arrest of the Whole Heart, by E. E. Laslett. The patient is a married woman, aged 40 years, who suffer from syncopal attacks associated with a slow, irregular pulse. The infrequency of the pulse is due to long intermissions lasting from two to five seconds. Tracings prove that the intermissions are due to an arrest of the whole heart and not to ordinary heart block. Tracings taken by Mackenzie's ink polygraph are given and the writer is enthusiastic as to the value of this instrument. The explanation offered of the phenomena in this case is that they are due to depression of the sinus rhythm by vagal inhibition. 2. A paper by Thomas Lewis on the Irregular Action of the Heart in Mitral Stenosis. An interesting discussion illustrated by tracings is given of some of the abnormal characters of the cardiac rhythm in mitral stenosis, and of the inception of new cardiac rhythms in heart block. 3. The Pathology of Paroxysmal Hæmoglobinuria: a Critical Review, by G. H. K. Macalister. The condition is the result of intravascular hæmolysis, which occurs when the blood serum becomes autolytic. There is in the blood a potential toxin composed of cytase and amboceptor which becomes active under certain conditions, of which the most prominent is external cold, which, however, is regarded as acting reflexly, the hæmolytic reflex travelling by the same path as the vaso-motor reflex. The relation of the condition to Raynaud's disease and to syphilis is discussed. The serum in this condition is isolytic as well as autolytic, and it is not necessary to assume any specific vulnerability of the red corpuscles. The ultimate source of the hæmolysin is not known. A useful bibliography is appended to this paper. 4. On the Frequent Failure of the Urine to Decompose in Cases of Pulmonary Tuberculosis, by W. Hale White and H. I. Janmahomed. It was found that the urine of patients suffering from pulmonary tuberculosis frequently has a high acidity, and that it may remain acid for prolonged periods. It also appears to have considerable bactericidal power. 5. Peripheral Birth Palsy, by E. F. Trevelyan. The various forms are described and illustrative cases are fully noted and figured. The prognosis and treatment are also discussed. 6. Clinical Observations on the Effects of Certain Drugs in Diabetes Mellitus, by Arthur J. Hall. The effects of codeine, opium, secretin, and aspirin upon the intake of fluid, the quantity of urine, and the daily output of sugar having been studied, the results are summarised in regard to each drug. 7. A Contribution to the Study of Congenital Family Cholæmia, by Robert Hutchison and P. N. Panton. The authors record two cases and give references to a case in the same family described by

Murchison in 1885. From a study of their own cases they conclude that one factor of considerable importance is the production of defective red cells, evidenced not only by the presence of cells of abnormal shape, size, and staining reactions, but also by increased fragility of the cells. This increased fragility is not the effect of the bile in the serum. 8. The Excretion in the Urine of Sugars other than Glucose: a Critical Review, by Archibald E. Garrod. Lactosuria, maltosuria, lævulosuria, pentosuria, and heptosuria are considered, and a useful account of each of them is given, with the tests by which they may be recognised and the conditions under which they occur.

New Inventions.

MASTOID GOUGES AND CHISELS.

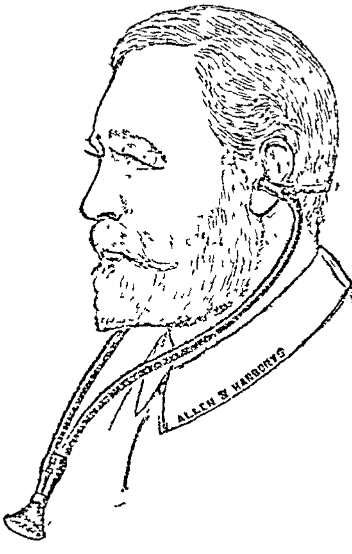


Messrs. Mayer and Meltzer of Great Portland-street, W., have made for me a set of gouges and chisels after the pattern shown in the accompanying illustration. They are particularly useful when operating in gloves. The finger-holes are so placed that, when holding the tool, the fingers do not block the view of the cutting edge. At the same time the force of the blow administered by the mallet upon the head of the gouge is transmitted to the point without dissipation and thus the great advantage of the straight over the curved or bayonet-shaped gouge is maintained.

DAN MCKENZIE, M.D. Glasg.,
F.R.C.S. Edin.,
Assistant Surgeon, Central London Throat and Ear Hospital.
Stratford-place, W.

A NEW BINAURAL STETHOSCOPE.

THE illustration shows a new form of binaural stethoscope, which we have tried and have found satisfactory. It is light and portable, since, owing to the smallness of its metal parts, it can be easily folded and carried in either the hip or coat pocket. It will be noticed from the illustration that the spring passes round the back of the head, and therefore cannot possibly interfere with the view of the auscultator while the instrument is being used. A further advantage is that there is no rotation of the ear-pieces, when the tubing and chest piece are moved during auscultation. The spring may require slight adjustment for comfort in some people, but this seems to be an easy matter. The price is 7*s.* 6*d.* complete, and the makers are Messrs. Allen and Hanburys, Limited, of Wigmore-street, W.



METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts, additional to those already announced in THE LANCET, received at the Mansion House or notified directly to us as having been collected on behalf of the Metropolitan Hospital Sunday Fund up to Monday, when the sum paid in was about £40,000:—

	£	s.	d.
St. Michael's, Chester-square	761	0	0
St. Peter's, Eaton-square	327	0	0
St. George's, Hanover-square	246	0	0
Essex Church, Kensington	243	0	0
St. Peter's, Cranley-gardens	237	0	0
St. Paul's, Portman-square	173	0	0
St. Peter's, Brockley	139	0	0
Christ Church, Mayfair	135	0	0
St. Stephen's, South Kensington	130	0	0
Wimbledon Churches	125	0	0
City Corporation	105	0	0
Holy Trinity, Paddington	103	0	0
Christ Church, Gipsy Hill	99	0	0
Brockwell Park Open-air Meeting	87	0	0
St. John's Wood Presbyterian Church	74	0	0
Holy Trinity, Marylebone	72	0	0
Hampstead Parish Church	71	0	0
Victoria Park Christian Evidence Association	67	0	0
Ferme Park Baptist Church	64	0	0
Holy Trinity, Wandsworth	62	0	0
German Church, Camberwell	55	0	0
Christ Church, Highbury	55	0	0

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—Demonstrations in Clinical Medicine will be given at this College throughout the months of August and September, beginning on Monday, August 9th, at 2 P.M., in the clinical theatre at the hospital. The subjects will be taken in the following order:—Mondays—Diseases of the Lungs. Tuesdays—Diseases of the Blood. Wednesdays—Diseases of the Digestive System and Children's Diseases. Thursdays—Diseases of the Nervous System. Fridays—Diseases of the Heart and Vessels. All members of the profession will be admitted on presentation of their address cards, and further particulars can be obtained at the College from the Warden, Mr. Munro Scott.

THE LANCET.

LONDON: SATURDAY, JULY 17, 1909.

The Imperial Cancer Research Fund.

IN another part of this issue we publish the seventh annual report of the Imperial Cancer Research Fund, and in it we find much to afford us both satisfaction in the work that has already been done and hope for the future. The only aspect of the report which is of a saddening tendency is the financial one; support of the Fund is very poor. When the Cancer Research Fund was established in 1903 nearly £50,000 were received, and in the following year a little more than half this amount, but 1905 saw a drop to £3000; in 1907 it was £500, and in 1908 it was under £700. It is true that the Bischoffsheim donation and some legacies have been received as well, but it is depressing indeed to find that for the last two years less than £1000 a year has been contributed to what is acknowledged to be among the most important research works in the realm of medicine. We hope that in the next report it will be recorded that a great increase has occurred in the amount of subscriptions, for the capital of the fund is being diminished year by year. We place the financial position of the Imperial Cancer Research Fund in the front of our remarks, for we feel that any relaxation of the energy with which the research is being conducted will be intensely regrettable, while the whole spirit of the annual report shows that such relaxation will only come from lack of money. The great help received by the Fund from the Royal College of Physicians of London and the Royal College of Surgeons of England in the granting of free laboratory accommodation has enabled the most rigid economy to be practised, but the time is approaching when these Colleges will be unable any longer to give this assistance, and then the need for further financial aid will become even more acute. The public, we trust, will soon come to the rescue.

The work that has been done up to the present is of vast importance and full of encouragement to all who know the difficulties in the way of research; but the results are not sensational, and it may be that the steady diminution in the financial support is due to the fact that so far no "cure for cancer" has been found and no certain clear and simple cause of it has been discovered. No one familiar with the points at issue expected any such immediate outcome, but the public was more sanguine. Much has, however, been done, and probably no step has been of more value than the discovery of the inoculability of malignant growths. This was first shown to be possible by JENSEN, and now the conditions under which inoculation is possible are so well known that success in inoculating a malignant tumour from one animal to another of the same species is almost certain. At one time many investigators refused to allow the carcinomatous nature of the inoculable tumours, but now we believe this is acknowledged by most observers. The value of this discovery consists mainly in the provision of an unlimited amount of material on which the action of drugs and other methods of treatment can be tried, and in which can be observed the changes occurring in a series of cancerous growths. The choice of the mouse as the chief animal for the study of cancer has been fully justified by the results obtained, and its small size and the little cost of maintenance are also strong arguments in its favour. In the study of the tumours produced by inoculation the important discovery was made that in one case the supporting stroma of a carcinoma underwent sarcomatous transformation, as was reported in the Third Scientific Report, and now we are informed that this change has been observed in a second case. But the new case differs in many important matters of detail from the first and therefore it is very valuable in helping to elucidate the factors on which this transformation depends, while the most evident factor in determining the development of a sarcoma from the stroma of the host has been shown to be the duration of the active growth of the implanted carcinoma. Another point which has been established is the immense variety of structure and pathological power exhibited by tumours, though the tumours of any one strain may present a general constancy. Two tumours apparently identical histologically may differ widely biologically. The constancy with which the various tumours retain their individual peculiarities shows that from the epithelial cells of one and the same organ many distinct kinds of malignant new growths may arise. This is fully in accord with the observations of the surgeon and the pathologist, who have noticed the immense clinical differences between two malignant growths which were histologically almost identical. The experiments have shown that these differences, though in part due to the constitutional differences of the hosts, are also in great measure the result of individual differences in the growths themselves. The most striking work, from the point of view of the prevention or cure of cancer, has been that on the manner in which animals may be rendered immune to the inoculation of malignant growths, and, as was shown in previous reports, both cancerous and normal tissues can be employed to effect this. But recent experiments have demonstrated that cells which have been killed or disintegrated in any way, as by chemical poisons or by physical agencies, such as heat or crushing, have lost entirely their power of conferring resistance. This is in marked contrast to what is seen in the case of diseases due to infective micro-organisms. In this connexion the action of radium upon normal and cancerous cells is of special interest, for if either be exposed to radium for an interval insufficient to cause any structural alteration in the tissues which is recognisable either by the eye or by the microscope, the tissues are found to have lost all power of growth and of conferring immunity. As up to now the parallel behaviour of normal and malignant tissues in these respects seems to exclude the probability of radium having a selective action on cancer tissues, it is well to moderate the hopes as to the possible therapeutic value of radium.

We entirely approve of the attitude adopted by the Fund towards a cancer census, for the data on which such a census would be founded are untrustworthy, and we are interested to see that the French Association for the Investigation of Cancer has come to the same conclusion. The Fund has been much assisted by the willingness with which Dr. J. TATHAM has placed the resources of the General Register Office at its disposal with a view to promote the attainment of greater utility and accuracy in the statistics of cancer, but there is necessity for great completeness of the data of mortality before any useful comparisons can be made between the figures of different countries. With the question of affiliation with the International Society for Cancer Research the Imperial Cancer Research Fund has also dealt wisely. The International Society is an association founded in Berlin, and it is intended to forward the holding of international congresses at which the facts and problems connected with cancer may be discussed. It was mentioned in the last annual report of the Imperial Cancer Research Fund that it had been decided not to join this society, even though the offer was made that the first international congress should be held in London. Efforts have been made to persuade the Fund to reconsider its refusal—indeed, His Majesty the KING was presented with a petition by the International Society asking that as patron of the Imperial Cancer Research Fund he would have this decision of non-participation altered—but the policy of the Fund remains constant. It is somewhat important that the attitude of the Fund should be understood, for those unacquainted with the facts may hastily conclude that it results from some want of willingness to coöperate with other countries. In the first place the Fund has always done its utmost to assist other workers, both in this and in foreign countries. To this end it has supplied material to many laboratories both at home and abroad—in fact, to more than 30 different laboratories in foreign countries; and a large number of foreigners have been received into the laboratories of the Fund in London. The staff of the Fund is already doing its utmost to assist international workers in the investigation of malignant disease. Dr. E. F. BASHFORD, the director of the laboratory of the Fund, and his committee are, however, agreed that the time has not yet come for an international congress on cancer. The facts requiring a congress for the unanimous recognition of their importance have still to be discovered, and much more good at present can be done by active coöperation in the distribution of material than by any congress. Inasmuch as the Imperial Cancer Research Fund is representative, by its executive and other committees, of some of the most important public bodies of this country, any congress held in London under such auspices would excite great anticipations on the part of the general public, which would not be fulfilled by the results. A premature congress can only do harm; but when the time is ripe, no society will be more anxious to coöperate with other nations than the Imperial Cancer Research Fund.

An Outbreak of Cerebro-spinal Meningitis.

ONE of the curious features of infective diseases is their tendency to periods of waxing and waning intensity, the causes of which are at present singularly obscure. In the case of the rarer epidemics the periods of prevalence afford special opportunities for the study of the nature of the maladies, and it is important that the occasions offered should be utilised to the full. A disease which in recent years has presented signs of increased activity, both in this country and in other parts of the world, is cerebro-spinal meningitis, and our knowledge of this affection has distinctly increased as a result of the studies to which it has been subjected by many observers. A recent contribution of considerable interest has been made by Dr. DAVID J. MORGAN in a pamphlet embodying an account of an outbreak of "spotted fever" which occurred in Swansea during 1908.[1] Dr. MORGAN raises several points worthy of more extended investigation. The whole number of cases with which he deals amounted to 63, and short clinical notes are given of all of them. The male patients outnumbered the female, as is usual in this affection, by 37 to 26 cases. Rather less than half of the whole number presented the peculiar rash from which the appellation "spotted fever" arises; but it must be borne in mind that typhus fever is also known by this name, and that the two maladies were not distinctly separated one from the other in days gone by. Hence it would be better, we think, to abandon this term for cerebro-spinal meningitis, the term being really more suitable for typhus fever, where the form of exanthem is much more constant. It is generally supposed that infection in cerebro-spinal meningitis is carried by the air and that the germs are inhaled by patients, the throat, nose, and tonsils being the portals of entrance. Dr. MORGAN'S observations do not bear out this supposition. Indeed, he found that cases of apparen direct infection were rare, only three instances occurring i which more than one member of a household suffered. Th distribution would seem to be more like that of enteri fever than of immediately contagious diseases, such as scarle fever or measles, and Dr. MORGAN suggests the alimentar canal as the portal of entry, supporting his view on th severity of the abdominal symptoms encountered, on th occurrence of necrotic areas in the liver, and on the constant enlargement of the abdominal lymphatic glands seer after death.

The resemblance presented by certain cases of cerebrospinal meningitis to enteric fever and the difficulties in diagnosis which may result are perhaps not generally recognised. Dr. MORGAN even finds that the serum of these patients may agglutinate typhoid bacilli in a dilution of 1 in 50, a phenomenon which would be looked upon as a positive reaction to Widal's test. Three cases out of five tested did so in his experience, and a fourth gave a positive reaction in rather less dilution. He suggests, indeed, that cases of cerebro-spinal meningitis have, on the strength of this peculiarity, been called enteric fever at various times, and quotes published instances apparently illustrating this source of error. It is of considerable importance that further light should be thrown on the frequency with which this serum reaction does actually occur, and we sincerely hope that those who have the opportunity of studying cases of cerebro-spinal meningitis will pay attention to this point and record their experiences. Apart from this, and from the gravity of the abdominal symptoms, in a certain proportion of cases there should not be any great difficulty in distinguishing the two affections. In cerebro-spinal meningitis the onset is invariably sudden, as is well brought out by Dr. MORGAN'S report, and the pain in the head is excruciating in character, not the dull frontal headache of enteric fever. Stiffness in the neck and retraction of the head are noted in over 90 per cent. of the cases of cerebro-spinal meningitis, and actual opisthotonos was recorded in 73 per cent. of patients. A further assistance in diagnosis is afforded by the occurrence of Kernig's sign—the stiffness of the muscles at the back of the thigh rendering it impossible to extend the leg when the thigh is flexed to a right angle with the trunk. Lastly, the examination of the fluid obtained by lumbar puncture will almost always lead to a correct diagnosis. It varies, it is true, considerably in different cases, from a thick creamy pus to almost clear straw-coloured fluid, but the meningococcus is usually to be found without difficulty.

---

[1] An Account of an Outbreak of Spotted Fever (Epidemic Cerebro spinal Meningitis) [illegible] David J Morgan, M.A., M.I [illegible] al Officer of Health of Swar [illegible] ewspaper Co., Ltd., High-street. 1909.

An interesting question with regard to treatment is raised by Dr. MORGAN, who was struck by the extraordinary divergence in the rate of mortality among cases treated respectively at home and in the isolation hospital at Swansea. Whereas 93 per cent. of the former cases died, in the hospital the death-rate was only 44 per cent. He attributes this remarkable difference to the fact that cases in the hospital were treated by lumbar puncture as a routine measure, whereas when home treatment was carried out members of the patient's family often objected to this procedure. No serum was used as a remedy throughout the epidemic, and Dr. MORGAN is inclined to attribute the amount of success which has been claimed for serum-therapeutics in this disease to the fact that the use of this remedy necessitates a preliminary lumbar puncture, to which, and not to the serum, the patients' recovery is due. At present we must conclude that there is not sufficient evidence available to decide as to the value of serum in cerebro-spinal meningitis. The remedy has not been very long introduced into practice and several brands of serum are prepared, the comparative efficacy of which has not been determined. We are therefore not prepared to admit that Dr. MORGAN'S experience by itself can be allowed to counterbalance such reports as have been made by others in this respect. Nevertheless, he makes out a good case for careful investigation as to the amount of good which is to be attributed to the serum and to the mere withdrawal of spinal fluid respectively. So far as we are aware, no harm has ever been traced to the injection of serum, so that there is no reason to feel reluctant to make trial of it. As the withdrawal of the spinal fluid will presumably be followed by the exudation of a fresh supply to take its place, it would be of interest to compare the bacteriolytic and opsonising values of the fluid withdrawn with those of the serum supplied for treatment. If this were done in a fair number of instances, some theoretical inferences might be drawn as to the probable value of serum as a local dressing for the spinal cord and brain, since it is as a local application that it has been found useful, authors being apparently agreed that ordinary subcutaneous injection is not of any value in this affection. Be this as it may, we congratulate Dr. MORGAN on the careful observation which he has made of the epidemic which came under his notice, and hope that his report will be widely studied in order that the points which he has raised may be investigated by others, and that advances may result in the diagnosis and treatment of one of the most fatal diseases which afflict European nations.

The Food of the Soldier.

FOR some time past a War Office committee has been considering the various questions concerning the health of the soldier produced physiologically by his food, training, and clothing, and as this committee is composed not only of military officials of great experience, such as Surgeon-General Sir ALFRED KEOGH, Director-General of the Army Medical Service, Surgeon-General Sir T. J. GALLWEY, Colonel S. P. ROLT, inspector of gymnasia, and others, but also of scientific men such as Sir F. TREVES and Dr. J. S. HALDANE, its conclusions deserve careful consideration at the hands of all interested in the well-being of the army. The third report of this committee has recently been issued, dealing with the oft-discussed question of the soldier's food. The report itself is short, consisting only of a dozen pages, but it is accompanied by six appendices, of which the first four contain details as to the analysis and packing of various brands of tinned meats supplied to the army by Major W. W. O. BEVERIDGE, R.A.M.C., assisted by Captain H. B. FAWCUS, R.A.M.C., and Major C. E. P. FOWLER, R.A.M.C. The fifth appendix by Major BEVERIDGE deals with the composition of emergency rations; and the sixth gives a useful statement of the various rations supplied to foreign armies, compiled by Lieutenant-Colonel W. G. MACPHERSON, R.A.M.C.

The report itself deals chiefly with the quantity, nature, and variety of the soldier's food under ordinary conditions—that is, his peace ration—and the arrangements that exist for his messing. From time to time various criticisms have been passed on the amount and kind of food supplied to our troops, generally more or less unfavourable. These comments have sometimes been the outcome of zeal for the soldier's welfare rather than of knowledge as to what is actually done for him, or, indeed, as to what work he himself has to do. It has often been supposed that he is much underfed, the assumption being that what is called the "ration"—i.e., a *pound of bread and three-quarters* of a pound of meat—is all the food that he is provided with under ordinary conditions in barracks in this country. In addition to this, however, he has a "messing allowance" of *3d.* a day, which is expended by the commanding officer of the regiment or unit, to the best advantage, in the purchase of vegetables, cheese, materials for puddings, and the like, as well as various articles that go to make up a breakfast menu, such as bacon, eggs, fish, and oatmeal. In any properly managed regiment the soldier gets a substantial breakfast, a meat dinner with two vegetables, and on most days of the week a pudding or cheese, as well as a tea meal with bread and cheese or butter. At supper-time he can always procure a meal in the regimental institute for 2*d*. or 3*d*., and in some corps a light supper of soup and bread, or the like, is provided gratis. The committee have worked out the food values of the various meals supplied in four different corps. These comprised a cavalry regiment, an English infantry battalion, a Scottish battalion, and an infantry depôt. There was not much variation between these different supplies; reckoning the food value in Calories per day per man, the dietaries supplied gave averages of 3478, 3340, 3248, and 3409 for the units in the order just mentioned. On an average for the whole four regiments, the protein supplied daily was 133, the fat 115, and the carbohydrates 424, stated in grammes. The committee have taken ATWATER'S diet for men doing moderate work—viz., one containing 125 grammes of protein and affording a total energy value of 3500 Calories, as the standard for comparison—and find that though the protein supplied in each case is sufficient, the average Calorie value does not quite reach 3500 in any of the four dietaries examined. But they point out that "this dietary is nearly always supplemented by food bought for supper at the canteen or elsewhere, and the pay of all soldiers is now sufficient to enable this to be done without hardship. The amount thus bought probably brings up the average energy value of the food to fully 4000 Calories, and at the same time gives elasticity to the diet, as each man can select the quality and amount of food which suits him." There can be no doubt that it is in practice wiser not to provide all the dietary according to regulation, but to allow a certain amount of individual choice. The soldier's pay is amply sufficient to enable him to spend 3*d*. or 4*d*. a day on extra food, and it has been found to be the case that he does actually, on an average, do so in the regimental institute. One important recent improvement is noted by the committee. The Army Council has now granted the messing allowance of 3*d*. a day to recruits as well as to trained soldiers. These newly enlisted "growing lads" have often been on short commons for a considerable time before enlistment and need feeding up to enable them to get through their work properly. Various barracks and depôts were visited, and it is reassuring to learn that, from an examination of the articles of food supplied, the cooking arrangements, and the messing books, the committee believe that, "taking into account the extra food which the British soldier is now well able to buy when he requires it, he receives, during peace, sufficient food; and ...... the quality and variety of the food are satisfactory." There is, we believe, no fixed scale applicable to warlike operations generally in the British army, each campaign being dealt with according to the circumstances of the country and climate, and modifications being continually introduced as a result of experience up to date. The committee analysed the South African war ration, taken at its minimum, and give its nutritive composition as: protein, 133; fat, 105; carbohydrate, 528, in grammes, producing in all 3903 calories. This is said to have been the minimum, and from all accounts it was certainly very often supplemented by fresh meat, grain, &c. The Calorie value is less than that of the Japanese war ration in Manchuria (4343) or that of the Russian army in the same campaign (4891). The committee consider that for men engaged constantly in marching and fighting, probably 3900 Calories would be insufficient unless supplemented from other sources. They recommend that experimental observations should be made on this point. This is an important matter which appears to need determination.

In regard to the arrangements that are made for messing the troops, the committee speak favourably of what is known as the "restaurant system." As originally introduced several years ago, this system was intended to give a much greater variety of choice in the food provided and to improve the manner of serving it, so as to make the meals more appetising and attractive to the soldier. It does not seem that in its entirety it has proved practicable to any great extent, but in a modified form the system is now in use in many regiments and depôts. Instead of the bare tables, coarse cookery, and wastefulness of the old barrack-room dinner, in very many regiments nowadays the men sit down to tables provided with a decent table-cover (generally of American cloth) and furnished with cruet stands, vegetable dishes, and so on. The joints are carved by trained carvers, so that not only is there much less waste, but the food is served in a more appetising way. There is also much greater variety in the cooking methods; two vegetables at least are provided, and nearly every day pies or puddings of some kind. This forms a great contrast to the old primitive ways, universal until some ten years ago, when the joint of meat was hacked about by the man in the mess who had the strongest wrist. The waste was then excessive, and no attempt was made to render the dinner, or other meal, anything but a hurried gorge, adjournment being made to the canteen as soon as possible to assuage thirst. Of late years the custom has been introduced of allowing beer and mineral waters to be served with the dinner meal; this practice has been found not only not to increase beer-drinking, but even to diminish it (the canteen being less resorted to), and has therefore tended towards temperance. It has been much appreciated by the men, and the committee recommend the general adoption of the practice.

Coming to the appendices the report by Major BEVERIDGE on the composition of tinned meats contains many observations of interest. Considerable variation, for instance, was found to exist in the composition of individual samples, the fat in corned meat tins being sometimes as low as 7 per cent., and sometimes as high as 60 per cent., reckoned on the dry contents. The committee, after experimenting on their own proper persons, conclude that meat with less than about 10, or more than about 15, per cent. of fat, is unpalatable to most men, from which it appears that more care should be taken in averaging the contents of the tins at the time of preparation. A curious point that has long puzzled manufacturers and storekeepers in charge of tinned-meat supplies has now been elucidated by Major BEVERIDGE'S experiments; tins of meat that have passed the tests applied by the makers and have kept good for months or even years, sometimes suddenly become blown and unfit for use. This occurrence could hardly be due to injury of the tin through rust, as, if so, the gas produced by putrefaction, consequent on entrance of air organisms, would find its way out and no blowing would result. Major BEVERIDGE, and with him Captain FAWCUS, have found that an organism may be present in the meat at packing, may not be destroyed by the so-called sterilisation, may remain inert for long periods if the tins are stored at a low temperature, and finally, may develop if the temperature reaches 37° C., or thereabouts. This bacillus is non-pathogenic to animals, but decomposes the meat and renders it unfit for consumption. As it does not develop much below the body temperature, meat might be contaminated by it and yet be kept for months without showing signs of decomposition or blowing if stored in a cool place, neither would the temperature of the "warm room," in which manufacturers deposit tinned foods for a short time as a testing chamber, be sufficient to cause growth of this bacillus. But if taken to a hot climate the whole consignment might speedily become unfit for use. The recommendation is accordingly made that the temperature of the fluid in which canned-meat tins are sterilised should be raised to 120° C. (248° F.), and that this should be kept up for one hour. This is a higher and more prolonged sterilisation than is, we believe, usually the practice at present, but in view of the observations of Major BEVERIDGE and his collaborators appears to us to be justified. It is satisfactory to learn that no boric acid or other preservative was found to be present in any of the tinned-meat samples, though the nitrates, derived from the pickling fluid, were sometimes in excess.

Annotations.

"Ne quid nimis."

THE NEW PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Mr. Henry Trentham Butlin was elected unanimously President of the Royal College of Surgeons of England at the meeting of the Council held on Thursday, July 8th, at the College. This event was generally anticipated, for Mr. Butlin's claims upon the titular leadership of his branch of the profession in this country are very strong. He is well known at home and abroad as an operating surgeon and pathologist. He has held almost every possible post in connexion with his College, he has won the Jacksonian Prize, he has delivered the Hunterian oration, the Erasmus Wilson lectures, and the Bradshaw lecture. But outside the College he has been equally prominent, for in addition to being consulting surgeon to and lecturer upon surgery at St. Bartholomew's Hospital he has been President of both the Pathological and the Laryngological Societies, member of the Senate and Dean of the Faculty of Medicine of the University of London, and Vice-President of the British Medical Association. Mr. Butlin brings, therefore, to his new and important post great experience both in organisation and in the exercise of authority, while his well-known happiness as an orator will stand him and his College in good stead. We offer him our best congratulations.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE seventy-seventh annual meeting of the British Medical Association will be held at Belfast on July 23rd, 24th, 26th, 27th, 28th, 29th, and 30th next, under the presidency of Sir William Whitla, Professor of Materia Medica and Therapeutics, in the University of Belfast. Fifteen scientific sections have been arranged and will meet daily from Wednesday to Friday in the Queen's College at 10 A.M.—viz., Anatomy and Physiology, Dermatology and Electro-Therapeutics, Hæmatology and Vaccine Therapy, Diseases of Children, Navy, Army and Ambulance, Hygiene and Public Health, Laryngology, Otology, and Rhinology, Medicine, Obstetrics and Gynæcology, Ophthalmology, Pathology, Pharmacology and Therapeutics, Psychological Medicine, Surgery, and Tropical Medicine. On Tuesday, at 2.30, Sir William Whitla will be inducted to the presidential chair, and on the same evening will deliver the presidential address in the Assembly Hall, Belfast. On Wednesday, July 28th, at 12.30 P.M., Dr. R. W. Philip will deliver the address in Medicine in the library, Queen's College. On Thursday, July 29th, at 12.30 P.M., the address in Surgery will be delivered in the library, Queen's College, by Mr. A. E. J. Barker. On Friday, July 30th, at 12.30 P.M., Sir John W. Byers will deliver the address in Obstetrics in the library, Queen's College. At 8 P.M. a popular lecture will be delivered by Dr. J. A. Macdonald. As the programmes throughout promise particularly interesting discussion, owing to the proposed attendance of men of eminence from foreign countries and various parts of the British Empire, the success of the meeting from every point of view is assured.

THE FEES OF OUR ANCESTORS.

UNDER the above title Mr. D'Arcy Power has recently contributed to *Janus* an interesting little paper on the emoluments of physicians at various periods. With the art of a practised writer he at once arrests his reader's attention by reminding him of two physicians whose custom it was never to receive a fee at all—namely, the "unmercenary" saints Cosmas and Damian. At the opposite extreme comes the fee which Mr. Power has omitted to recall—namely, that received by Democedes of Crotona, who as a prisoner was in the service of Darius Hystaspes at Susa. Darius had dislocated his foot at the ankle-joint and Democedes was called in after the failure of an Egyptian surgeon. His treatment was successful, and he was thereupon presented with two golden fetters, a delicate allusion to his position. Having delighted Darius by asking him "whether he meant to double his punishment," that monarch told him to go through the harem as the man who had saved the king's life. The ladies each gave him a golden vessel piled up with *staters*, so many of which fell on the floor that the slave who conducted him made a handsome fortune by picking them up. He was afterwards called in to treat Atossa the Queen for a mammary ulcer which he succeeded in curing. Such patients, however, as the Great King and his consort do not fall to every man's lot, though in quite modern times the high feudatory princes of India have paid comparable fees. In the Middle Ages men were more mercenary, and Mr. Power gives an amusing quotation from John of Arderne (*circa* 1370) as to the methods of bargaining with a patient. Arderne's highest fee for the cure of fistula in ano was £40 down, a suit of robes, and 100*s.* per annum during the life of the patient. Patients in the Middle Ages were no more ready to pay their fees than now, and Gilles de Corbeil, a celebrated twelfth century physician, points out in language which must surely strike an answering chord in the heart of the present Chancellor of the Exchequer, that the rich man must pay in accordance with his wealth, though he adds as a saving clause "if his mind is as wide as his purse" then—

> "Aggravet hic medicina manum: sumptus onerosos
> Exigat: hic positos debet transcendere fines."

In another place he remarks that it is as well for the physician to demand his fee before the patient is well—

> "Tutius esse reor, quod certe novimus omnes,
> Dum dolet accipere, vel munere posse carere."

Mr. Power concludes his paper with an account of eighteenth-century fees. Physicians like Radcliffe and Mead charged a guinea; country apothecaries charged much less and made their money chiefly by the sale of medicine. Mixtures, as Mr. Power reminds us, were sent out as draughts in one ounce phials with a cork which sometimes had one pill in a box stuck on to it. Draught and pill cost 1*s.* 9*d.* As many of our readers will remember, the directions were written on a slip of paper attached to the neck of the bottle, and such a draught in the half light of a sick room bore a ludicrous resemblance to the human inhabitants of a Noah's Ark as manufactured in about 1860, up to which time the custom of separate draughts endured. Readers of Swift will remember the story he tells of Stella. "A quaker apothecary sent her a vial, corked; it had a broad brim and a label of paper about its neck. 'What is that,' said she, 'my apothecary's son?'"

MORTALITY FROM MEASLES.

Satisfactory as have been the results on public health and longevity of improved sanitary administration in England and Wales during the last 30 years, there are still many features in our national mortality statistics which, without undue pessimism, clearly point to distinctly preventable waste of life, especially among infants and young children. The weekly returns of the Registrar-General, for instance, have recorded during the first six months of this year no fewer than 6381 deaths from measles in 76 of the largest English towns. Of these deaths it may safely be estimated that more than 90 per cent. were deaths of infants and children under the age of five years. In the corresponding six months of 1907 and 1908 the fatal cases of measles in these 76 towns did not exceed 4596 and 2692 respectively. The exceptional mortality from this disease during the first half of this year has probably been mainly due to unfavourable meteorological conditions, but it is an unquestionable fact that the generally improved sanitary condition of the English population during recent years has not effected any considerable reduction in the death-rate from measles. The annual rate of mortality from measles per 1,000,000 of the English population, which was equal to 379 in the ten years 1871–80, increased to 441 in 1881–90, was 414 in 1891–1900, and has been 311 in the first eight years of the current decennium. It should, moreover, be borne in mind that these death-rates from measles, calculated on the population at all ages, understate, for comparison in the several periods, the present true rate of mortality from this disease, if corrected for the recent marked decline in the proportion of young children in the English population. It cannot be doubted that the case-mortality of measles mainly depends upon watchful nursing and care during convalescence; it is therefore not surprising to find that measles mortality is, to a great extent, confined to those classes in which careful nursing and treatment are neglected or are practically impossible. The class-mortality statistics issued by the Registrar-General for Ireland, relating to the Dublin registration area, throw valuable light on class-mortality from measles, and suggest the desirability for similar statistics on a larger basis. During the two years 1907–08 the deaths from measles in the Dublin registration area were 304, of which only 23 occurred among the professional, independent, and middle classes, estimated to number 104,624 persons of all ages, whereas the number occurring during the same period among the general-service class (excluding artisans and petty shopkeepers), consisting of an estimated population of 154,279 persons, was 223. The calculated death-rate from measles in these two sections of the Dublin population during 1907 and 1908 was more than seven times as high among the general-service class as among the professional, independent, and middle classes. The deaths from measles in England and Wales during the past eight years of the current decennium have averaged more than 10,000 per annum, and will this year very considerably exceed this number. It is impossible to doubt that the large majority of these deaths are distinctly preventable by careful nursing and after-treatment. Without venturing entirely to attribute the remarkable decline of the mortality from scarlet fever in recent years to hospital isolation and treatment, the experimental trial of hospital isolation and nursing for measles naturally calls for serious consideration. In connexion with this subject it is interesting to note, in the recent appeal by the London Fever Hospital for financial support, that the hospital treatment of measles has recently been adopted at that institution. The result of this experiment cannot fail to be helpful in the consideration of the desirability for the creation of facilities for the hospital treatment of measles as a possible means of checking the present waste of child-life caused by the persistent mortality from this disease.

THE REPORT OF THE LADY ALMONER TO ST. THOMAS'S HOSPITAL.

Not long ago we devoted a leading article to a consideration of the report made by Miss Norah B. Roberts to the recent Poor-law Commission upon her inquiry into the extent of hospital abuse in London, and we mentioned her recommendation that fully trained lady almoners should be appointed at all hospitals in order to limit its occurrence as much as possible.[1] The report of Miss A. E. Cummins, lady almoner to St. Thomas's Hospital, upon the work of her department from March, 1908, to March, 1909, affords a timely confirmation of Miss Roberts's opinion, and is a document which should receive wide circulation amongst other hospitals and careful study by those responsible for their management. The lady almoner's department at St. Thomas's was instituted "to check the abuse of the out-patient department by patients who are either in a position to pay for treatment or who are too poor to benefit by any assistance other than that obtainable through the Poor-law; to ensure as far as possible that all out-patients to whom treatment is granted shall benefit to the full by that treatment; and that no time, consideration, or money shall be withheld, either by the patient or by charitable agencies, to enable the patient to coöperate with the hospital in carrying out the prescribed treatment." The work has now been established for four years and has been extended considerably since its inception, its plan being that only as many cases as can be dealt with thoroughly shall be undertaken at all. No routine inquiry concerning wages, rent, and so on, has been found of value in adjudicating upon the suitability of an applicant for hospital relief. In order to carry out the thorough personal investigations that are necessary the coöperation of existing charitable agencies has been secured, a plan which it will be remembered was recommended by the recent Commission for the solution of other problems in poor relief. Miss Cummins is gratified at the help that she found available in this work, the demand for which almost seems to create the supply. It has been possible to visit 2942 patients at home as against 170 during the first year of the work, which, although it only represents a fraction of the patients attending the hospital, shows a gratifying and progressive vigour in the life of the department. Particular pains are taken not to multiply the number of visitors to any one family, for the reason given epigrammatically in the following words: "The industrious woman has no time to receive constant visits from church, chapel, rent collectors, and charitable agencies. The idle may be quite willing to pass their time in this way, but should not be encouraged to do so." A chief object of the work is to help people to help themselves, and it has been found in several cases that by inducing a breadwinner to save up money to buy a surgical appliance or extra nourishment for his wife the habit of saving has been established, to remain after the immediate necessity has passed Special efforts are directed to the provision of such necessities of treatment as proper food and fresh air, for it is recognised that a vast amount of the skilled advice given to hospital out-patients must necessarily be wasted if they are left to their own devices to carry it out; but each is expected to contribute to his cure according to his means. "Cases," says Miss Cummins, "are not classified as deserving or undeserving ...... but as helpable or not helpable. Most cases prove helpable in the long run, though not always on the lines first expected." A special section of the report is devoted to phthisical patients, and a system for their management has been evolved from a study of the family life and progress of 200 cases. When the home conditions are very deplorable the case is referred to the Poor-law authorities, a procedure which should not be neglected by hospital almoners. In more suitable cases other relief agencies are asked to provide extra food in the homes of patients, who are taught the virtues of fresh air and the evils of spitting. All very early cases have been sent to sanatoriums, but an encouraging experiment has been made in one instance by the erection of an open-air shelter in Camberwell, and it is hoped that the plan may be extended for the treatment of patients unable to leave their homes. The report of the cases convicted of hospital abuse affords striking reading; we quote the most flagrant. "A. B., medical casualty, 28, married man, said he rented a flat at 10*s.*, and earned £2 as a clerk. His wife looked after the two children and did the housework. No club." He was refused medicine on the strength even of this statement, and a letter was sent to a private practitioner who had attended him and who answered: "A. B. is in partnership with his father in trade. To my certain knowledge the father gave £14,000 for an estate and a freehold site for a church, &c., for which he was publicly thanked by the bishop. A. B. lives very comfortably in a rather small house, where they keep a maid-of-all-work and an old woman to look after the children." It would be interesting to know whether such a despicable application for relief as this comfortably situated person made to the hospital is actionable; certainly it seems to be an attempt to obtain money—or its equivalent—under false pretences. Fortunately, such cases by no means represent the majority of out-patients, many of whom "overstate rather than understate the family incomes, possibly from a feeling of pride." Some difficult cases were met with of patients going from one hospital to another, causing deplorable waste. In more than one case a lover of medicines was found to be attending two institutions simultaneously for the same disease. The last part of this instructive report deals with the help given by the lady almoner's department to the maternity department, help which included a limited number of free meals to nursing mothers. Miss Cummins deprecates a wide extension of this plan: she "cannot fail to acknowledge the want of backbone that is increasingly evident amongst the working-classes," for the charitable aids, the free meals for school children, and other free gifts to the poor are coming to be regarded as the working-man's right. We feel constrained to admit a substantial foundation for her complaint and commend to other hospital authorities the system upon which her department is worked—namely, to subsidise and not to supplant the efforts of the poor on their own behalf, with the object of fostering their spirit of independence whilst ministering in a rational manner to their infirmities.

---

THE TUBERCULOSIS CRUSADE IN WESTERN IRELAND.

IN "A Holiday in Connemara" Mr. Stephen Gwynn, M.P. for Galway and a well-known *littérateur*, has put on record his impressions of the work of the Gaelic League in the "Crusade against Tuberculosis" among a section of the Irish population peculiarly liable to the inroads of disease. "One by one," he says, "the young and strong are being smitten; and the disease (tuberculosis) is being cruelly multiplied by others again, who, having gone to the towns of America or Great Britain, with lungs adapted by generations of heredity only to the soft moist air of Western Ireland, have fallen an easy prey to the white pestilence, and, broken down in health, come home for a few years, to cough out their lives in poison among their nearest friends; to linger out in cabins where no window is made to open, where folk sleep terribly crowded, and where the earthen floors become perfect nests of the bacilli." This passage was written as lately as last autumn, but it is cheering to reflect that then and for some time past the most thorough prophylactic measures had been initiated in Connemara and the districts of the neighbourhood. Fascinating is Mr. Gwynn's account of how Dr. Seumas O'Beirn of Tawin, himself a Gaelic speaker, came to the conclusion that typhus fever and tuberculosis seemed to be endemic in those districts where Irish alone was spoken, and where consequently practical English ideas on health had not penetrated into the popular consciousness. To him apparently belongs the honour of having first diverted the energies of the Gaelic League, which aims at reviving and using the Gaelic tongue, into a practical channel, for it was he who first conceived the eminently sensible idea of lecturing on health and anatomy in Gaelic—as Erse is universally called in Ireland—to those Irish peasants to whom English still remains a foreign language. Gaelic, as Mr. Gwynn points out, is as yet a language so new to technical phraseology, that explanation must of necessity be made in the very simplest terms. But Dr. O'Beirn announced none the less a series of lectures on the human body and the origins of disease, to be delivered in the Irish tongue and illustrated with lantern slides. He began his course in Kilmilcin in the Joyce Valley, and the quick-witted peasantry crowded to hear him, and were emulous to pass examinations in the laws of health. Among other things, probably, they were taught that windows should not be mere panes of glass, but should open. Indeed, we understand that the value of fresh air, in a country rich in that commodity, was impressed at every turn on the eager students who thronged to the Kilmilcin lectures. Shortly afterwards the Gaelic League took up the cause, a distinguished Dublin surgeon having invited their assistance in an inaugural sessional lecture at one of the Dublin hospitals as lately as last autumn. The Celt is so intelligent that there is no limit to the possibilities of reform when he sets his heart upon attaining it. The appeal to the Celtic imagination is being made in more ways than one. Dr. O'Beirn, for instance, has written and sustained the leading part in a propagandist medical play ("An Dochthuir"), which deals amusingly with the difficulties encountered by an English-speaking medical man in an Irish-speaking round of practice. The drama has been acted by local players in Connemara. An ingeniously conceived vehicle for the dissemination of hygienic doctrine, it might well be imitated by all those who fight unenlightenment in any rural district of England.

SALT AND SMOKE.

FOR some time past the public taste has been gradually growing in favour of the mild-cured article, with the result that at the present moment strong salted or smoked foods are not in evidence as they used to be and are rarely called for. The ham and the bacon must be mild cured, and even butter must be fresh and absolutely without a salt flavour. This preference for the so-called mild-cured article has undoubtedly furnished an excuse on the part of caterers for the use of stronger antiseptics than salt or smoke, and antiseptics which are, comparatively speaking, tasteless, or at any rate which add no special flavour to the food. The old-fashioned antiseptics, salt and smoke, are thus sharply distinguished from modern antiseptics, inasmuch as the former not only preserved food but served also as condiments. In the case, however, of certain preserved foods, although the salt may be left out, the smoke must be retained, as otherwise the food loses its individuality The kipper, for example, is inseparable from a smoky flavour, as is also dried haddock or dried salmon. We have heard that a "smoke essence" is employed to impart the kind of palatability associated with properly smoked food, but such practices, coupled with the use of antiseptics, would readily account for the regrettable fact that cured articles of diet are not now up to their former standard. Assuming that the mild-cured article, and as a particular example we may choose butter because it is an indispensable article of the dietary, is free from objectionable antiseptics, it is still left more helpless against the attacks of micro-organisms than were the old-fashioned cured foodstuffs. Experiments have, in fact, shown that the addition of salt to butter is a factor of great importance from the point of view of germs. In unsalted butter the growth of micro-organisms is more vigorous and continues for a longer time than is the case with salted butter. Mycelial fungi if present disappear entirely after a while in salted butter, while in fresh or unsalted butter they multiply rapidly. The quality of butter appears to be improved by a small percentage of salt (say 2·5); it encourages the development of a flavour which makes butter an attractive article of food and it acts as a safeguard. Altogether there would appear to be certain valid reasons for thinking that the public preference for the mild-cured article may be an error of judgment, and there certainly is much to be said in favour of the old policy of preserving foods by salt and by smoke.

THE NATIONAL ASSOCIATION FOR SUPPLYING FEMALE MEDICAL AID TO THE WOMEN OF INDIA.

As their religion will not allow them to be attended by a male, the caste prejudices of India prevent a very large proportion of the female population obtaining medical aid in any of the numerous hospitals and dispensaries, the majority of which are State institutions. As the Government of India could not see its way to provide female aid, Lady Dufferin, during her husband's tenure of the office of Viceroy of India, nobly stepped into the gap and created a fund, which has been since known as the "Countess of Dufferin's Fund," for supplying female aid to the women of India. In the twenty-fourth annual report for 1908, just published, the association shows steady and satisfactory progress in providing relief not only for purdah but other women. The present president, Her Excellency Lady Minto, has during the year under review inspected many of the hospitals under the Fund, and has interested herself in representations made by the Association of Medical Women in India (which were referred to in THE LANCET of March 13th, p. 780), whereby they claim a more independent control of zenana hospitals. The central committee cannot at present, however, hold out any hope of a so-called "medical service" being formed under which lady doctors would enjoy the privileges of pension and other advantages which are attached to the regular Government services. The association has now in its employ 52 lady doctors of the first grade (qualified for British Medical Register), 87 of the second grade (Indian qualifications), and 529 hospital assistants, or third grade. Of female students at present training, 22 European and native ladies are shown as training for the full M.B. course, 91 as assistant surgeons, and 101 as hospital assistants, nurses, midwives, and compounders. The backbone of the whole Dufferin Fund is medical tuition; it cannot get on without medical women and its numbers are limited. But the work done is exceedingly good, and the present report shows a grand total of slightly under 2,250,000 patients (women) treated in 1908.

THE WET SUMMER.

As though exhausted by its unusually brilliant efforts of the two months preceding, the weather was a dismal failure in June and has been no better in the first part of July. Never since meteorological records have been systematically recorded has the opening of summer been so gloomy and cold, and seldom so rainy as it was during last month in London and some other parts of southern and south-eastern England; while over the kingdom generally, although the lack of warmth and sunshine was less striking in relation to the average, the month ranks as one of the most unsatisfactory Junes for many years. The chief cause of the great chilliness was the persistent predominance of winds from some point between north-west and north-east, accompanied by a very cloudy or densely overcast sky. The natural result of this ungenial combination was that while the temperature during the night-time was only slightly below the average, nearly all the days were remarkably cold for the time of year. The thermometer approached the normal on extremely few occasions. The normal maximum shade temperature for June in the south and south-east of England is between 65° and 70°, but, as will be gathered from the subjoined table, the mean of last month's maximum readings was only about 60°. Over by far the greater portion of the kingdom the 70° mark was not reached at all, and even in London, where a warm June sends the thermometer up to 70° or above day after day, it was only touched twice—on the 17th and 19th. No June except the miserably cold and wet one of 1879 has had such a low maximum in the metropolis for at least 40 years. Had the sky been fairly clear the temperature would doubtless have been considerably higher in spite of the cold winds, but it was so persistently clouded that the sunshine in London and some other parts of the south-east was the most meagre recorded in June since the automatic instruments were established in 1881. After Westminster had enjoyed 220 hours of the most brilliant sunshine in April and 297 hours in May, the June figures dropped to 91 hours—from an average of between nine and ten hours per day to one of about three hours. Such an extraordinary difference as that between May and June is probably without parallel in this country. The deficiency of sunshine was also very great in the Midlands and along the south coast, but at Jersey it was very trifling and not particularly large in the north-west of England and in North Wales. Manchester was not so badly served by the sun as Westminster. Over the greater part of England the month was much more rainy than usual, but the quantity varied a good deal, and some spots received less rain than during a normal June; at Buxton there was nearly an inch less. To enable a month to give such abnormal weather as did the one under consideration the positions and routes of the cyclones and anticyclones must also be abnormal. Last month the barometrical conditions were, in fact, generally quite different from those usually obtaining at this time of year. During an average June the space between the Azores and France or Germany is covered by a vast anticyclone of varying intensity, while the large cyclones from the Atlantic travel in a general easterly or north-easterly direction with their centres either between Scotland and Iceland or to the northward of Iceland, thus causing a flow of air over this country mainly from the south-west or south. During almost the whole of last month, however, there was an anticyclone over the Icelandic region, which frequently extended southward over the Atlantic off the west of these islands, and with such a distribution of barometric pressure the wind over this country must necessarily come from the Polar regions. Why such a displacement of the high and low pressure systems should sometimes occur is at present, and will probably remain for a long time yet, a meteorological mystery.

DEATH FROM OVERLYING.

THE National Society for the Prevention of Cruelty to Children recently prosecuted a Brighton woman for neglecting her four children, all under the age of 16 years, in a manner likely to cause them unnecessary suffering. The youngest of the children was a baby four weeks old, and the chief ground upon which the society based its case was the woman's drinking habits, and it was alleged that when in such a condition she could not perform her maternal duties properly. The other children, all of tender years, seemed to thrive on their surroundings; and in the absence of any direct evidence of wilful neglect—which the chairman of the bench said must be continuous neglect—the prosecution, after a two-day hearing, failed, the case being dismissed. It goes without saying that in many ways the children must have suffered from a certain amount of neglect, but while the magistrates could not see their way clear to convict they could have at least given the woman a severe caution and a warning as to her future conduct. But she was allowed to leave the court without the slightest admonishment. The sequel must surely have afforded a shock to the complacency of that lenient bench, for nine days later the same woman appeared before the Brighton coroner's court, the same baby, now six weeks old, having been found dead in bed by the side of its parents on the morning of July 8th, seven days only after the police-court proceedings had concluded. Attention was, of course, drawn to the proceedings in the police-court, and the coroner, Mr. J. E. Bush, expressed his astonishment that the magistrates did not censure the woman. Two women gave evidence a mitting that the mother of the dead child had given way t drink, but said that she was sober on the night before th morning the child was found dead. This fact seems to hav saved the woman from being committed for trial under th provisions of the Children Act, which makes a drunke parent responsible for the death by overlying of a chil for the jury expressed the opinion that the child died fro overlying. The death of the child within a few days of th prosecution by the National Society for the Prevention Cruelty to Children shows that this excellent society wa fully justified in its action. There have been many simila cases in Brighton, and only a smart sentence, when evidenc is strong, will act as a deterrent. It is among the childre of the slothful and the drunkard that infantile mortalit exerts its greatest influence.

IMPROVEMENTS AT BATH.

ON July 10th Sir Malcolm Morris was the guest honour of the Bath corporation, which had invited him t open formally an open-air drinking fountain and colonnad that will enable visitors to take the waters in the Institutio Gardens. Sir Malcolm Morris performed his duties, down t the drinking of the first glass from the new source of supply with enthusiasm for the merits of the Bath waters, fo which he professed a personal gratitude, but he also too the occasion to speak very plainly on the supineness i the past of their owners. It was a happy choice which le the corporation to invite a distinguished physician to perfor this function, the more especially since the occasion mark the establishment of wise relations between the medica men of the town and the administration of the baths, as i witnessed by a recent election of Dr. R. Carter and Mr A. L. Mackenzie to serve on the baths committee. Thi fact was commented upon with approval by the mayor, Mr W. J. Knight, after the luncheon following the proceeding in the gardens. At the same feast Sir Malcolm Morri did not fear to tell the city of Bath a few home truth about the backwardness of English health resorts in providing attractive accommodation for their visitors, and he did so in terms that the managers of spas elsewhere would do well to take to heart. "If you will take my message, Mr. Mayor and Corporation," said their chief guest, "and are not so slow in your improvements, you will rival the great spas of Europe in a way no other place can do. But you always think, and you talk for hours and hours upon ways and means. ..... You have a duty to perform to the nation and not to your town alone. If your water contains some material of benefit to human beings your duty is to use it. You have all the things to your hand here. Do it, and do it properly and at once. I have nothing to do with Bath and its rates or with your jealousies and squabbles, which I take it exist in every provincial town in the world, but ...... you possess a remedy for the cure of chronic diseases, and yet you don't supply a sufficient amount and sufficient attractions for the people who should use it." This was, perhaps, the straightest speaking that a luncheon party has ever received from its guest of honour, and we will do the city the credit to say that its corporation received the message in excellent part. The mayor, indeed, pointed out in extenuation that ratepayers had always to be reckoned with, but the enlightened action of the Chamber of Commerce, coupled with the active support of the local branch of the British Medical Association in carrying through the recent improvement, was, he submitted, a good earnest of further advances in the interests of their city. He confessed that he was in agreement with what their guest had told them. We may, perhaps, now hope for such another revival at Bath as was attempted in that city about a generation ago. Even though Bath shall never know again the glories of the eighteenth century, we are assured of the investment value to the city of money spent in the proper development of the spa such as has now been done in the provision of an open-air service of the waters.

A VEGETABLE SOURCE OF IRON.

M. P. J. Tarbouriech and M. P. Saget, in the *Bulletin des Sciences Pharmacologiques* for May, describe some experiments which they have made to find a vegetable drug containing a relatively high proportion of iron. As a result they have been able to show that the dried root of one of the docks, *Rumex obtusifolius*, contains 0·447 per cent. of iron, a proportion greatly in excess of that yet found in any other plant. Further experiments showed that the iron is present in organic combination. It is a difficult matter to isolate and identify such complex substances, owing to the readiness with which the inorganic element is split off, but evidence was obtained that the compound is analogous to the ferric derivatives of the nucleones. These substances, as shown by Siegfried, are present in milk and in the muscles and other tissues of the body, and it is thought that iron, calcium, and phosphoric acid are carried from one part of the body to another in the form of nucleone derivatives. It is believed by many pharmacologists that a large proportion of the iron administered in the inorganic form is not assimilated in the body, and on this account various organic compounds of iron have been introduced into medicine, including the glycerophosphate and the so-called "peptonate" of iron. The administration of iron in the form of a nucleone derivative as present in this species of rumex would appear to offer advantages over the other compounds of iron, and this view is supported by results that have followed the administration of the powdered rumex root by the mouth.

THE RÔLE OF THE PERINEAL BODY IN CHILDBIRTH.[1]

THAT the perineal body *per se* plays a relatively unimportant part in the support of the pelvic viscera has long been recognised by most anatomists. It is not surprising, therefore, to find that cases of complete rupture of the perineum can and do occur without any or with a relatively slight descent of the pelvic viscera. Matthews Duncan long ago called attention to this fact, but as he pointed out quite correctly, rupture of the perineum, although it does not cause prolapse, yet markedly facilitates it. He compared the rôle of the perineum in prolapse of the uterus to that played by it in childbirth, and contended that just as a rigid perineum prevents the escape of the fœtal head so an intact or a partially torn perineum prevents the conversion of a case of prolapse of the second degree into one of complete procidentia uteri. Dr. R. H. Paramore cites Matthews Duncan's conclusions with approval, but would have us believe that the part played by the perineum in childbirth is neither necessary nor good. That it is not necessary he holds to be shown by the occurrence of normal labour in the case of its previous rupture, and that it is not good he maintains because he thinks its presence promotes over-stretching of the pubo-rectalis portion of the levator ani muscle—viz., those fibres which take origin from the back of the pubes, and encircling the rectum, are attached in the middle line in the ano-coccygeal raphe, and so produces marked weakening of the pelvic floor. The muscles inserted into the perineal body are of little importance, comprising a comparatively small bundle of fibres of the pubo-rectalis portion of the levator ani and the internal and external sphincter muscles of the anus. The great stretching that all the structures in the perineum undergo during childbirth is shown by the fact that the distance from the anterior margin of the pubo-rectalis muscle to the fourchette at the time of the birth of the child's head through the vulva measures some five inches, of which the stretched perineal body itself accounts for three inches or more. Dr. Paramore maintains that the tension of these thinned-out perineal tissues determines a forward projection of the fœtal head, and at the same time the plane of the vulvar outlet becoming extremely oblique and approaching the coronal plane, is in this way considerably removed from the plane of the pelvic outlet which is almost horizontal in direction. The posterior extremities of these two planes are therefore at a considerable distance from one another, while their anterior extremities are close together. The actual distance separating their two posterior extremities is usually some five inches. The view put forward ably by Dr. Paramore is that since these apertures are not in planes parallel to one another an ovoid body such as the head of the fœtus passing through them at the same time must, while it is passing through one with its long axis perpendicular to the plane of that aperture, pass with its long axis placed obliquely through the other. From this he argues that when the head is traversing the vulvar outlet with its long axis at right angles to that plane it can no longer be passing in the same and most advantageous manner through the opening of the pubo-rectalis muscle, and therefore this muscle is subjected to an undue degree of stretching. If, however, the perineum is destroyed by tearing, then the forward projection of the head produced by that body no longer occurs, the head does not pass through the opening of the pelvic floor with its long axis placed obliquely to the axis of that plane, and therefore the pubo-rectalis portion of the levator ani muscle is not stretched to an excessive degree. On these grounds Dr. Paramore holds that the perineal body plays an important and pernicious part in the production of over-stretching of the pelvic floor. The argument is an ingenious one, but we think that Dr. Paramore has lost sight of the fact that the head is undergoing a marked movement of descent during the time that extension is taking place. It is not correct to assume, as apparently he does, that the head passes through the two planes, that of the pelvic aperture and that of the vulvar outlet, at the same time; it does not. Indeed, at the time that the suboccipito-bregmatic diameter is engaged in the vulvar outlet, if we assume that the distance from the anterior margin of the pubo-rectalis portion of the levator ani muscle to the fourchette is five inches, as the author allows, the whole head has already passed through the aperture of the pelvic outlet, since even in a greatly moulded fœtal head the distance from the bregma to the chin measures not more than five inches and usually less, while at this stage of delivery the back of the neck, or at any rate a portion of the back of the head well below the level of the occipital protuberance, is in contact with the under surface of the pubes. Unfortunately there are no frozen sections available of the latter part of the second stage of labour which would enable us to determine with certainty the exact relation of the head or of the neck of the fœtus to the plane of the pelvic outlet at the time that it is engaged in the vulvar outlet. Barbour's section of the early part of the second stage does indeed bear out Dr. Paramore's contention, since it shows that the head is already slightly extended, to a greater degree at any rate than during pregnancy, at a time when the forecoming part of the head is only just appearing in the vulva. On the whole, we are inclined to think that Dr. Paramore's hypothesis is a correct one, but at the same time we feel that he has rather over-exaggerated the amount of distension of the levator ani muscle and of the pelvic floor thus produced, and that he regards the action of the perineal body in this matter as more harmful than it is in reality.

CHICAGO CAMPAIGN FOR CLEAN MILK.

THE sanitary authorities of the city of Chicago have been setting a good example in regard to the milk-supply. In 1908 an ordinance was passed prohibiting the sale of milk unless it was obtained from cows that had been tested satisfactorily with the tuberculin test. As, however, such a rigorous measure could not be at once applied, it was decided that for a period of five years milk from cows that had not been thus tested could be sold in Chicago if it was pasteurised. This latter stipulation was all the more necessary as the sanitary condition of many of the dairy farms is very defective. The water from the wells supplying these farms has been analysed, and when found to be contaminated the milk-supply was stopped until a new and safe well had been dug. Farmers are also advised how to conduct their work on sanitary lines and are compelled to notify cases of disease occurring in or about their farms. During the present year there has been a re-inspection of all the farms, and wherever the orders of the Chicago health department have not been carried out notice was served that the supply of milk would be cut off in five days. This delay of five days enables the city dealers to obtain a supply from another source. The city authorities appeal to these dealers and to the general public to help in bringing pressure to bear upon the dairy farmers, and urge that everyone should make inquiries as to the place whence the milk is obtained which it is proposed to buy. Thus during the month of March last the milk from 60 different farms had to be kept out of the city because the regulations of the health department had not been observed. But it is not only necessary to see that the milk introduced into a town is wholesome when it arrives, measures must also be taken to prevent its contamination while exposed for sale and after it has been purchased. In regard to the latter, advice is given throughout the poorest districts in Chicago to indicate how ice-boxes can be made in which a bottle of milk can be kept at such a small cost that the poorest can afford the outlay. Any box about 18 inches long and 13 inches wide and deep will do. In the centre is placed a circular pail or can 8 inches in diameter which is high enough to hold a quart bottle of milk. Round this pail there must be a cylinder to protect it and so that it may be lifted in and out. In the pail the milk-bottle stands surrounded by ice; below and all round the box is filled up with sawdust. The addition of a little soda will prevent rust. For a lid the best thing is to fasten together some 50 old newspapers. Anyone can make such an ice-box as this. It will hold four 8-ounce feeding-bottles and will not cost a penny a day in ice. The poor of Chicago are being taught to preserve in this manner the milk used for the feeding of infants and children. The construction of such an ice-box, even where the materials have to be bought, should not amount to more than about a shilling. In regard to the sale of milk there is an excellent regulation which reads as follows: "Between May 1st and Nov. 1st all windows of shops shall be provided with fly- and dust-screens and all doors shall be provided with self-closing door screens." Now that the pernicious action of flies and the rôle of dust as a disease-carrier are better understood the importance of the regulation will be appreciated. It is time that all foodstuffs, but more especially milk, should be protected from dust and flies. Pastry and sweets are especially attractive to flies, and a law or regulation should compel the dealers in such articles to cover them over with fly- and dust-screens. That the sanitary authorities of so important a city as Chicago have taken action in this respect is encouraging, and we recommend their example to the attention of the sanitary authorities in this country.

REMOVAL OF AN EMBOLUS FROM THE COMMON ILIAC ARTERY WITH RESTORATION OF THE CIRCULATION.

IN the *Journal of the American Medical Association* of May 22nd Dr. John B. Murphy of Chicago has reported a case in which he performed a novel and daring operation. A married woman, aged 41 years, was admitted into hospital on April 29th, 1909. She had enjoyed good health until five years before this time, when she suffered from acute rheumatism, the attack having been repeated two years later. This second attack left her subject to dyspnœa. Four days before admission she was seized with sharp pain in the left side of the upper part of the abdomen, and later the pain extended down to the pelvis. Pleurisy was diagnosed and she was given opiates. The pain in the upper part of the abdomen disappeared, but that in the lower region continued. On the following day she vomited five or six times. An hour later, at 12 noon, she felt pain in both legs, which became cold and remained so until the following morning, when the pain in the right leg ceased and the limb regained its normal temperature. The left leg remained cold; the thigh was blue and the foot was pale and "shrivelled." Over the middle of the thigh the skin showed large blue blebs. On admission the pulse was 82 and the respiration 26; the temperature was not recorded. There was a double mitral murmur. Pulsation was absent in the left femoral artery. The left lower limb was undergoing dry gangrene up to four inches below Poupart's ligament, where there was a line of demarcation. It was decided to remove the embolus that was occluding the iliac artery. Nitrous oxide was given for 30 seconds and an incision was made downwards from an inch above Poupart's ligament parallel to the femoral artery. When the incision had extended through the skin and connective tissue the anæsthetic was stopped, and the dissection was continued until the femoral artery was exposed for a distance of two and a half inches. It was œdematous and easily separated from the neighbouring structures. Two provisional catgut ligatures were passed around it with an aneurysm needle, but were not tied. They were used to elevate the artery, which was incised in its long axis for one inch. The artery was completely thrombosed. With a delicate forceps a bifurcated clot one and a half inches long was drawn from below upwards. Then fresh arterial blood came from below, evidently from a collateral circulation through the profunda. A finger was then placed on the lower end of the artery inside the ligature loop so as to compress the vessel and stop the flow of blood. With the forceps Dr. Murphy began to extract the clot from the proximal side, but could not empty the artery. He then introduced a delicate spoon and withdrew more clot, but no blood flowed. Then he introduced a No. 6 soft catheter for a distance of seven and a half inches. He withdrew it filled with grumous blood débris, but no arterial blood followed. He reintroduced it, but could not force it through a resistant body at the end. He introduced a ureteral catheter; it met resistance at the same distance, but was forced through the thrombus and passed up for a distance of 19 inches, thus catheterising the abdominal aorta. A small quantity of arterial blood followed its withdrawal. A uterine sound was then introduced. It met with resistance at a distance of 7½ inches. It was forced half an inch farther and on its withdrawal much grumous thrombotic débris came away but no arterial blood. It was pushed a little farther and met firm resistance. No blood followed its withdrawal. It was introduced for a third time and with a little additional force at a distance of eight and a half inches seemed to pass into a free space. This was followed by an intense flow of embolic débris and fresh bright blood like that from a normal femoral artery. The finger was then inserted into the proximal ligature loop to stop the bleeding. With a fine silk suture on a curved conjunctival needle rapid continuous suture of the arterial incision was performed. On removing the digital pressure there was a little oozing between the second and third stitches. Two additional stitches stopped this. Pulsation could be felt throughout the femoral artery. After removal to bed the patient complained of pain in the toes and ankle, the first sensation in these parts after the embolism. The circulation became established below the line of demarcation. Amputation was performed four days later four inches below the line of bleb formation and the flap survived. The trunk of the femoral artery was found occluded by a loose non-adherent clot. Considering the success with which the clot was removed from the common iliac artery it is unfortunate that the operation was not performed until four days after the embolus was arrested at the bifurcation of the abdominal aorta.

THE PUBLICATIONS OF THE RESEARCH DEFENCE SOCIETY.

IN THE LANCET of July 3rd we printed a report of the annual meeting of the Research Defence Society, and that report shows clearly the large amount of work which is being done in teaching the public what are the real aims and methods of physiologists in making experiments on animals. One of the most valuable of the means adopted by the society to educate the unlearned in physiology has been the publication of pamphlets on various aspects of the subject, and we have received four of these pamphlets which have been recently issued. The first is on the need for the use of dogs in scientific experiments, and it is written by Professor E. H. Starling. The dog has been recognised as the friend of man for many centuries, and the affection subsisting between dogs and their owners is very great; it is therefore not surprising that a feeling should exist that it is desirable that some other animal less closely associated with man should be employed for experimental purposes, and attempts have been made to render it illegal to experiment on a dog under the Vivisection Act. Professor Starling in the pamphlet mentioned points out the reasons why the dog is indispensable for scientific purposes. It is only in academic laboratories that research can go on, for there only do we find the men the main object of whose life is the advance of science, and who are stimulated in their researches by the necessity of continually teaching the main truths of science, and in such institutions only is it possible to obtain the assistance of the brighter students as co-workers and to train them as future leaders in science. If therefore the investigations carried out in these scientific institutions involve the use of animals for experiment, the animals must be such as can be kept in a healthy and normal condition either in the laboratory itself or in buildings in close proximity, limited in their area and the nature of their surroundings by the fact that in most cases they have to be placed in the middle of populous centres. In isolated experiments it may be possible to employ the ordinary animals of a farm, such as bullocks, sheep, pigs, and goats, but they are not available for ordinary physiological and pathological investigations. Professor Starling emphasises the fact that no real distinction can be drawn between purely utilitarian and purely scientific experiments. The fact elicited by a scientific experiment to-day may be the starting point of most important utilitarian methods to-morrow. If animals are required for experiment, they must be such as can be kept in health and comfort within the limits of the laboratory. The only animals available are the frog, mouse, rat, guinea-pig, rabbit, dog, cat, and monkey. The frog is chiefly of value because, being a cold-blooded animal, its tissues survive a long time after removal from the body. The guinea-pig, rat, and mouse are of chief value for inoculation when large numbers of experiments have to be made; for instance, in the rooms of the Imperial Cancer Research Fund some 10,000 mice are kept. The rabbit is of great service, but its digestive system is very different from that of man, and for this and other reasons its physiological value is not so great. The monkey is invaluable for investigations on the brain and central nervous system, for in this respect it is closely allied to man, but for this very reason physiologists are loath to use it for experiments where animals lower in the scale will suffice. The organs of the cat are too small to permit of much experimental interference, and the dog therefore is the only animal whose omnivorous diet closely resembles that of man, whose general conditions of life allow it to remain healthy in a laboratory, and whose organs are of a size convenient for experiment. Professor Starling quotes many series of experiments which could only have been made on dogs, and points out the great results which have followed. He shows, moreover, that it is in the interest of nearly all the experiments that no pain should be felt by the animal, for pain would vitiate the results observed. Dr. A. Gardner Robb of Belfast has contributed a pamphlet on the value of antimeningitis serum in the treatment of epidemic cerebro-spinal meningitis. He makes it clear that by means of many experiments on the lower animals an antimeningitis serum was obtained from the horse. Before the use of the serum the mortality of epidemics varied from 69 to 80 per cent., with an average of about 75 per cent. After the use of the serum the mortality has been very much less, varying, he says, from 13 to 42 per cent. The improvement following the use of the serum is seen not only in the absolute mortality but also in the greatly reduced course run by the cases, and the number of serious complications and sequelæ has also been much diminished. It could in the first instance only have been obtained by experiments on animals, and the doubts with regard to its value may have to be tested by repetition of some of these. An important pamphlet is that on the anæsthetics used in experiments on animals. It is pointed out that more than 96 per cent. of all experiments on animals in this country are of the nature of inoculations and do not require any anæsthetic—in fact, they do not deserve to be called operations. All true operations on animals in this country are done under anæsthesia, and the pamphlet discusses the efficacy of morphia and chloral as anæsthetics or analgesics. By the replies of witnesses before the Royal Commission on Vivisection it is conclusively shown that each of these drugs can abolish absolutely all pain if the drug is given in a sufficiently large dose. The fourth pamphlet is a reprint of an article on the advance in knowledge of cancer by Dr. E. F. Bashford, Director of the Laboratories of the Imperial Cancer Research Fund. It demonstrates clearly that our exact knowledge of the conditions in which malignant disease appears dates only from the commencement of experimentation on animals. We have quoted enough to show that in issuing these pamphlets the Research Defence Society is doing good work, for they will show to all unprejudiced readers that physiologists and pathologists do not torture animals, and that though they insist upon the need for experiments on animals they do their best to mitigate any sufferings of the animals, and that in the vast majority of cases there is no suffering at all.

ACUTE INSUFFICIENCY OF THE SUPRARENALS.

IN an interesting paper published in the sixth number of *Contributions from the William Pepper Laboratory of Clinical Medicine* of the University of Pennsylvania, Dr. R. S. Lavenson records a case showing a group of symptoms due to acute insufficiency of the suprarenals, and points out that this condition, which is regarded as of considerable importance by French clinicians, has been but little studied in other countries. The patient was a widow, aged 44 years, and a native of Ireland. For two years she had been subject to occasional attacks of abdominal pain with vomiting, and during that time she had lost slightly in weight. One morning, shortly after breakfast, having been previously in comparatively good health, she had an attack of vomiting with some epigastric pain. This pain became more severe and vomiting was more frequent. Towards the evening she became slightly delirious and was admitted to the University Hospital under Dr. Stengel. The vomiting had ceased on admission, the temperature was 95° F., the respirations were 48, while the pulse could not be felt. The patient complained of epigastric pain and there was tenderness in this region and in the loins. On physical examination, apart from this tenderness and slight rigidity of the abdominal wall, there was little to be discovered. During the early part of the next day the breathing became of Cheyne-Stokes type. Under vigorous stimulation the patient reacted slightly, her temperature rose to 100° at noon, but her pulse was never palpable, and she died at 8 o'clock in the evening—i.e., about 36 hours after the onset of the symptoms. At the necropsy there were found to be chronic interstitial nephritis, chronic fibrous myocarditis, chronic catarrhal gastritis, fatty degeneration of the liver, with commencing periportal cirrhosis. There was also chronic pancreatitis, with acute interlobar suppurative changes. Both suprarenal veins were thrombosed and the suprarenals were in a condition of acute hæmorrhagic necrosis. Cultures made from the pancreas showed staphylococci, colon bacilli, and a bacillus positive to Gram which was not identified. Those made from the suprarenals were negative. The interpretation suggested by Dr. Lavenson is that the patient had probably suffered from the chronic pancreatitis for some years, and that a recent acute suppurative inflammation had been engrafted on this, leading to thrombosis of the adjacent suprarenal veins. Dr. Lavenson also gives an interesting summary of the etiology and pathology of the condition, with references to the recorded cases. With two exceptions all the cases have been associated with suprarenal hæmorrhage or with so-called adrenalitis, the latter being generally a necrotic rather than an inflammatory process. The two exceptions are a case of Janowski, in which the suprarenals formed small abscesses above the kidneys, and one recorded by Stursberg, in which suppuration was found in both suprarenals of a woman suffering from Pott's disease. The peculiar blood-supply of these glands derived from three sources—viz., the aorta, the renal artery, and the arteries of the diaphragm, the capillaries and venules uniting to form a single vein—has suggested that simple alterations in the blood-supply or the blood pressure may be determining factors in the production of hæmorrhage into the glands, and this explanation has been put forward in regard to the suprarenal hæmorrhage so frequently observed in the newly born. Chronic heart disease and pulmonary disease leading to chronic venous congestion have both been regarded as causes of suprarenal hæmorrhage. Similarly, it has occurred after conditions leading to a great increase in blood pressure—e.g., after repeated epileptic fits. The tendency to hæmorrhage in asphyxia has caused it to be regarded as a possible factor, especially in the newly born. In some cases organisms have been isolated from the suprarenals, and experimentally hæmorrhagic and destructive lesions have been produced in animals by bacterial and other poisons. The condition has also been noted in connexion with purpura, surface traumata, and with burns. A few cases have occurred in association with suppurative changes in adjacent organs as in the one shown by Dr. Lavenson himself. Clinically the following classification is suggested: first, cases with sudden onset and epigastric pain and tenderness followed by abdominal distension and death within a few days. The resemblance between this type and cases of acute hæmorrhagic pancreatitis is obvious. Secondly, an asthenic type, associated with a profound asthenia ending in death within a few days. Thirdly, a nervous type, with convulsions, coma, delirium, or the occurrence of a typhoid state. Fourthly, cases of sudden death; pathologically these are usually found to be due to hæmorrhage. Fifthly, cases with a purpuric eruption or with hæmorrhages into the abdominal viscera. Some of the cases present symptoms of more than one of these groups. A tumour from the hæmorrhage into the suprarenal has been felt in a few cases, and the *ligne blanche* of Sergent is described as being of diagnostic value; it consists of a white line produced by stroking the skin with the finger, but other observers agree that it is to be found in other conditions associated with vaso-motor relaxation. Dr. Lavenson's paper affords within short compass an interesting study of this condition, and since it presents certain facts in regard to suprarenal disease in a somewhat new light should serve to draw attention to the possibility of this explanation in some obscure cases of death from acute abdominal disease.

THE TINNING OF METALS.

IN 1908 the Home Office issued certain draft regulations which it was proposed should apply to factories in which the process of coating metal articles with a mixture of tin and lead or lead alone is carried on. In consequence of receiving from the traders concerned a considerable number of objections in regard to these regulations the Secretary of State ordered an inquiry to be held, and Mr. Edward Thornton Hill Lawes, barrister-at-law, was appointed a commissioner for the purpose. His report has just been issued, based upon a vigorous attempt to reach the truth and to solve the problems involved. Previous reports referred chiefly to the question of the operatives keeping themselves in a state of cleanliness, while certain experiments showed that lead chloride was present in the fumes given off from the tinned article, and conclusions were drawn to the effect that the danger of the process was largely due to this fact. Mr. Lawes, while not accepting that poisoning is entirely due to the fumes, admits that the effects of the metallic lead dust and unwashed hands must now be regarded as inconsiderable, compared with the danger of inhaling fumes containing lead chloride whether in the form of vapour or dust, as lead chloride is very soluble in the human system. The draft regulations were intended only to apply to the process of common tinning in which lead is used, and therefore the making of tin plates—iron plates coated with tin—and pure tinning were exempted. The making of "terne" plates, which includes the use of lead, was also exempted because the special process adopted involved no harm. It would appear that in the common tinning process lead cannot be dispensed with, but there is reason for believing that by the adoption of an efficient draught near the scene of the operation the risk of lead-poisoning is reduced to a minimum. Other simple measures, as, for example, the use of soap and a nailbrush and a protective apron by the employed, are enjoined in order to guard against poisoning by actual contact with the metal or metallic dust.

THE LEAGUE OF MERCY.

MORE than a thousand guests were present at the garden party which was given by the Prince and Princess of Wales to the members of the League of Mercy at Marlborough House on July 7th. Preceding the reception in the garden some 140 of the presidents and lady presidents of the League met, under the presidency of the Prince of Wales, in Marlborough House, when a report of the work of the League during the past year was read by Mr. J. Harrison, M.V.O. His Royal Highness in his address said: "The progress of the League of Mercy, as measured by the amount handed over to the King's Hospital Fund, with contributions made to hospitals in the home counties, and the numbers engaged in the work of the League, has during the past year shown no sign of decrease. Last year £19,000 were given to the King's Fund, as against £1000 in the first year of our work, while £3495 were contributed to local hospitals outside the area of distribution of that Fund, being 50 per cent. more than in the previous year. The League is thus realising the intention with which it was inaugurated. It is familiarising the humbler citizens of London and the suburbs with the work of the hospitals, and securing in some measure their coöperation in the maintenance of these institutions." Subsequently the Prince and Princess, with Princess Mary and Prince Henry and Prince George, entered the grounds of Marlborough House, where the honorary secretaries of the League, Lord Wolverton, Sir William J. Collins, M.P., and Mr. Harrison, presented to their Royal Highnesses the ladies and gentlemen who had been awarded the Order of Mercy.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

IN view of the nearness of the long vacation the day schools sub-committee presented to the London Education Committee on July 14th a preliminary report showing what has been done in the direction of enlisting the aid of the hospitals for the medical treatment of school children in the metropolis. The medical officer for education estimates that 43,746 children out of 740,728 are suffering from affections of the eyes, ears, and skin. 39 hospitals have replied to the inquiries of the Council; six have not expressed any desire to coöperate; four hospitals for children and six others desire to help as far as existing rules permit; six hospitals have specifically stated that they can take additional cases. All these decline payment, whilst 16 hospitals are prepared to accept a money payment in one form or another. The replies also indicate that the hospitals would be opposed to any interference by the Council in the management of the institutions, and there is a general feeling that the Council should not ask for any special privileges for the children, although some of the hospitals have expressed their willingness to afford such facilities. The Education Committee decided to recommend the Council to accept the free offers of the Central London Ophthalmic Hospital, the London Hospital, the Paddington Green Children's Hospital, the Queen's Hospital for Children (Hackney-road), the Royal Westminster Ophthalmic Hospital, and the Victoria Hospital for Children; and to enter into negotiations with the authorities of other hospitals to provide treatment in the out-patients' department for a payment not exceeding £50 a year for each additional medical assistant (working one-half day a week) needed for the treatment of the children, together with a sum of 2*s.* for each child so treated, to cover the other expenses incurred by the hospitals.

GUY'S HOSPITAL MEDICAL SCHOOL.

ONE of the most interesting of the annual functions connected with the London medical schools is the summer distribution of prizes followed by a garden party in the grounds of Guy's Hospital. This year the event took place on July 8th and its success was as great as any of its predecessors. The prizes were presented by the Duke of Devonshire in the Physiological Theatre, where Mr. Cosmo Bonsor, treasurer of the hospital, occupied the chair. The Dean in his report was able to give a satisfactory account of the school work during the past year, and he included in his remarks a statement that must have been no less satisfactory to the medical part of his audience and to the parents present whose sons will shortly be dependent on medicine for a livelihood. The Dean said: "It is interesting to note that this period of depression in the medical profession seems passing away, and there is no doubt that at the present time the demand for qualified men far exceeds the supply. Applications are being daily received from provincial hospitals unable to get the medical officers they require, and the income that can be made by the recently qualified man is certainly much higher than it was a few years ago. In the circumstances, therefore, it seems desirable to point out to the public that the profession of medicine holds out at the present time better prospects than it has for some years past, and that an income can be made in its ranks which compares favourably with that to be made in many other professional careers." The Dean concluded his remarks with a plea for further endowment of medical education, which was endorsed by the Duke of Devonshire's subsequent speech. After the prizes had been presented, the company joined those who had been unable to gain admission to the crowded theatre in the grounds, where a good band and a fortunate sun rendered the garden party a very pleasant affair, enlivened as it was by the presence of many lady visitors and a display of academic costume.

DR. William Stirling, professor of physiology, Dean of the Medical Faculty, and pro-Vice-Chancellor of the University of Manchester, has been nominated the delegate to represent the University of Manchester at the quincentenary of the University of Leipsic, which will be celebrated from July 28th to 31st.

THE Lord Lieutenant for the county of Bedford has signed the commission of Surgeon-Lieutenant-Colonel Rowland Hill Coombs, M.D., 3rd Battalion the Bedfordshire Regiment (Special Reserve), to be his Deputy Lieutenant.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies stated that 2 cases of plague with 1 death were reported during the week ending July 8th.

GUY'S HOSPITAL DENTAL SCHOLARSHIP.—Mr. F. N. Doubleday, L.D.S. R.C.S. Eng., has been awarded the Guy's Hospital Travelling Scholarship of £100.

IMPERIAL CANCER RESEARCH FUND.

THE annual meeting of the General Committee of the Imperial Cancer Research Fund was held on Friday, July 9th, at Marlborough House, H.R.H. the PRINCE OF WALES, President, being in the chair.

Amongst those present were the Knight of Kerry (Vice-President), Sir William S. Church, Sir R. Douglas Powell, Sir Henry Morris (honorary treasurer), Sir John Tweedy, Sir Charles Morison-Bell, Mr. H. T. Butlin (President of the Royal College of Surgeons of England), Mr. Gerard Fiennes, Mr. Henry L. Florence, Mr. Robert Littlejohn, Sir Henry G. Howse, Mr. L. Neumann, Dr. J. Rose Bradford, Sir John McFadyean, Dr. T. T. Whipham, Dr. Arthur Newsholme, *Mr. Edmund Owen, Dr. F. W. Andrewes, Dr. J. F. W.* Tatham, Dr. E. F. Bashford (general superintendent and director of the [illegible] Dr. M. Haaland, and Mr. [illegible]

Letters express [illegible] were read from Mr. A [illegible] Waldorf Astor, and Sir Julius Wernher (Vice-Presidents); from the Duchess of Bedford, Lord Rothschild, Sir Thomas and Lady Glen-Coats, and others.

SEVENTH ANNUAL REPORT.

Report of Executive Committee.

During the past yea[illegible] the authorities of the [illegible] Berlin, in which it has [illegible] should reconsider the [illegible] International Society, [illegible] gress should be held [illegible] opinion that the decis[illegible]

[illegible] extent to which the [illegible]

and is beyond the reach of many [illegible] Fund, would be debarred from [illegible] research. Recognising that such [illegible] it has been the aim of the general [illegible]

[illegible] superintendent. It has been found impossible to concede all the requests, but the following gen[illegible] to pursue their researches in [illegible]

country. [illegible]

Report of the General Superintendent.

Dr. Bashford's report commenced with a reference to the annual report of the previous year, [illegible] went on as follows:—Exper[illegible] conclusion deducible from [illegible] chief dangers of cancer lie [illegible]

[illegible] lignant new growths of the [illegible] with our experience in man, [illegible] apply the results obtained by [illegible]

[illegible] its statistical importance was emphasised, but also the relation that [illegible] ancer in mice of known [illegible] s frequent occurrence of [illegible] als, and, by analogy, in [illegible] As is well known, crude [illegible] cancer occurring in the stocks of breeders of mice and rats have been held by many writers to [illegible]

[illegible] constant [illegible]

[illegible] correspond closely with the biological characters, and in particular we [illegible]

[illegible] killed or disintegrated in any way such as by chemical poisons or [illegible]

[illegible] in this respect between normal [illegible]

[illegible] hese respects [illegible] action upon [illegible] 1905 in the [illegible] the existence [illegible] disseminate [illegible]

[illegible] animals during the processes of successful grafting, immunity, and spontaneous healing respectively. While corroborating the general results already published—viz., that the specific connective tissue and vascular scaffolding supplied by a normal is not supplied by an immune animal—they show that the entire connective-tissue system of the animal responds during the processes both of spontaneous healing and of immunisation. The consequence is that any subsequent inoculation fails to elicit the response necessary for continued growth. It is not intended to deny that changes in the blood plasma accompany the acquirement [illegible] it is difficult to conceive of [illegible] ing without this intervention [illegible] the connective tissues pro [illegible] e not solely responsible, and [illegible] moral nature but to a large [illegible] forded of the negative results [illegible] to obtain an anti-cancerous serum.

From the general hospitals of England and Scotland details of 13,000 cases of cancer which have been submitted to microscopical examination have been collected. For the present the collection of clinical and pathological data from these sources has been suspended, as it is considered that the number already obtained promised to afford as satisfactory results as would an even larger number. This line of enquiry was embarked upon because of its critical bearings upon the interpretation and pathological value of the data on which the national mortality statistics are necessarily based. The wisdom of the conclusion arrived at in 1902 not to undertake a cancer census in the British Empire on the lines of that made in Germany on Oct. 15th, 1900, has been justified not only by our own later experience but also by the fact that since that date most other countries have recognised its futility. Incidentally the collection of clinical and pathological data from hospitals has demonstrated that the taking of a census of cancer patients in the general population, as advocated and practised abroad, is an absolutely worthless tabulation of data vitiated by an exaggeration of all the fallacies inseparable from data of mortality. In a recently published circular the French Association for the Investigation of Cancer expresses its determination not to undertake one of these "extensive and futile cancer censuses" for the same reasons as influenced the Imperial Cancer Research Fund in 1902. An improvement in the value of the statistical investigations of cancer is only to be expected from an improvement in mortality statistics as a [illegible] e data. The necessity for [illegible] of mortality applies still [illegible] between the statistics of [illegible]

Comparisons between different countries will only be made profitable by an all-round raising of the standards of accuracy and completeness of the mortality statistics as a whole with which those of cancer are inseparably bound up. The willingness with which Dr. Tatham has placed the resources of the General Register Office at the disposal of the Imperial Cancer Research Fund with a view to promoting the attainment of greater utility, accuracy, and completeness of statistics of cancer for England and Wales, deserves to be placed on record. The collaboration of a National Statistical Office has not been vouchsafed to the same extent to similar enquiries out of England and Wales.

The collection of data from outlying parts of the Empire has been continued, particular attention having been directed again to the importance of seeking for peculiar forms of chronic irritation associated with the occurrence of malignant new growths in native races. In this connexion a new and most interesting observation has been reported from Eygpt—viz., the occurrence of cancer of the skin of the chest on the triangular area of skin left bare by the clothing worn by the Felaheen.

Reviewing the results of seven years' work on the comparative and experimental investigation of cancer, one is struck by the difference between the nature of the problems before us seven years ago, and of those now being considered, as well as by the freedom one feels in investigating the problems presented to-day, without the incubus of having to consider them from the standpoints of the many hypotheses now proved to be untenable. I do not think that too much is claimed by asserting that the arduous labour of the past seven years is gradually effecting, and in several respects has actually effected, a complete [illegible] ancer problem. But it has done [illegible] biology. Seven years ago no one [illegible] kept growing for a period four tir [illegible] animal. But to-day the number of [illegible] propagated separately, make it theoretically possible that the majority of the tissues may be so grown and segregated. In other words, a living animal can be analysed into many of its living component tissues. The finer relations of various kinds of tissues to one another have been revealed by the application of the new methods. The biological alterations which living mammalian cells may undergo suddenly, as well as gradually, under the influence of experimental conditions, can now be studied. These and many other achievements in the field of general biology are the most important practical fruits which have accrued from the experimental study of cancer, upon which they have only indirect bearings. Ultimately they are bound to be of far-reaching general [illegible] y they are merely the weapons tha [illegible] Their further development and [illegible] purely biological problems will probably precede the solution of many of the problems surrounding the nature and causes of cancer.

While some chance opportunity may yield results of immediate practical moment, the outlook on therapeutics in the meantime is in the direction of preventing dissemination or metastasis. The means of explaining why inoculated cancer can undergo spontaneous cure have been greatly enriched by the acquisition of fresh strains of propagable tumours behaving in a variety of ways in this respect, and presenting all gradations from some growing progressively in every animal inoculated, to others which, while developing for a time in every animal, are ultimately got rid of in all cases by the active resistance which the tumours induce against themselves.

The development of the investigations in [illegible] with their increasing requirements has been [illegible] a parallel extension of the laboratory accomm [illegible] Royal [illegible] only w [illegible] the lat [illegible] isposal of the Im [illegible] expansion of the laboratory accommodation, without which it would have been impossible for the investigations to have acquired their present manifold and extensive character. During the first year of active work the staff consisted of the Director and one colleague. To-day there are four official assistants to the Director, six voluntary scientific workers in the laboratory, and a staff of 14 other laboratory assistants. The investigations have grown to an extent which fully occupies the entire accommodation in the present premises. The future of the investigations depends not only upon whether the Royal Colleges can continue to support them on the same generous scale as heretofore, but also upon whether they can provide for the exigencies of future development.

Report of the Honorary Treasurer for the Year Ending June 24th, 1909.

It is my unpleasant duty to report that since 1903 no less a sum than £9915 14s. 1d. has been taken out of capital account in order to meet the recurrin [illegible] nses and receipts.

In spite of [illegible] d, due to the munificent gift of Mrs. [illegible] I regret to say that the expenditure during the financial year just ended exceeds the revenue from investments by £2194 12s. 6d. The Fund commenced the year with a balance of £656 10s. 6d. in hand on current account, but it finished with an overdraft of £744 15s. 6d. The deficit is chiefly attributable to the great cost of publishing the last scientific report, which in size is greatly in excess of any previous report and contains a considerable number of elaborate and valuable illustrations.

The total outlay in issuing this scientific work amounts to £1510 8s. 8d., of which £1071 6s. 1d. is charged to this year's account. There has also been a considerable increase in the amount of research work carried on in the laboratories throughout the last year as compared with all former years, except the latter part of the year 1907-08. This was rendered possible by the additional workrooms and other space accommodation which the two Royal Colleges gratuitously put at the disposal of the Fund. More scientific workers have thus been provided for; and the payments made to them and the increases in the salaries of certain of the original subordinate officials, whose experience in the laboratories has rendered their services increasingly valuable, have led to an increase of £265 11s. 10d. in the salaries and wages of those engaged in the laboratories. Besides the large increase in the scientific report account, and the increase just referred to in salaries and wages, the only other items of expenditure which show increases are printing and postage, on which there is an excess over last year of £14 5s. 7d., and miscellaneous office expenses, in which there is the slight increase of £4 11s. 4d. In other items of expenditure considerable decreases appear.

It is a regrettable coincidence that in a year when a very large additional expense has been incurred in the publication of the latest scientific report the amount received by the Fund in donations and legacies has fallen lower than in any previous year. The total sum contributed to the Fund throughout the whole year is only £781 5s. 6d., showing a depth of material indifference on the part of the public to which the worst of the preceding years had not even approximately descended.

Thanks, however, are due to several very constant and continuing supporters, as will be seen at a glance on looking to the list of contributions for the year. In this list will be found the names of several good friends to the Fund who have subscribed, even to their seventh or eighth contributions; whilst the Worshipful Company of Carpenters have doubled the amount of their annual subscription.

Unless a substantial sum is shortly forthcoming in the way of legacies or donations it will be necessary for the trustees to realise at least £1000 to cover the overdraft.

Moreover, owing to the change in the ownership of the Examination Hall where the research work at the present time is still being carried on, it will very soon be requisite to obtain new premises and to build new laboratories. Hitherto, not a penny has been spent on building or equipment—thanks to the munificent generosity of the two Royal Colleges.

What the disposition of the Colleges towards the Fund, by way of their continuing to find adequate working quarters, may be, it is not possible for me to predict; but, seeing that the Colleges will themselves have to make very large outlays of money in building a new Examination Hall, the Imperial Cancer Research Fund must be prepared to provide a new home for itself in the immediate future.

Sir **WILLIAM CHURCH** moved the adoption of the report. He said: At the last annual meeting of the Fund the third scientific report was in course of preparation and continued to occupy much of the time of the staff until shortly before its publication in October last. This year it is not the intention of the committee to publish any scientific report; the work through the year has been mainly a development of the investigations recorded in our last report and as yet is not sufficiently complete for publication. The experimental work which has taken place during the past year confirms the opinion expressed some years ago that the course of cancer as it can be observed in the laboratory agrees with that which occurs in man, and forms a sound foundation for studying the disease as it is met with in the human species. As it has already been amply demonstrated that all malignant growths of the mamma occurring in mice can be experimentally propagated in other mice, only those instances of the disease which presented special features differing from those which had been transplanted in former years were propagated. Such growths numbered 28 out of 107 which were met with in the course of the year, being in all instances cases of spontaneous cancer. The breeding experiments from mice derived from cancerous stocks have been continued, but the numbers are as yet insufficient to render a detailed analysis of the figures useful for the comparison of the frequency of cancer in mice with a cancerous ancestry with the frequency of cancer in mice generally.

One of the carcinomatous tumours propagated during the past year has thrown light on the connexion between implanted carcinoma and the development of sarcoma in the tissues of the host. In this particular instance the development of sarcoma follows almost constantly upon successful inoculation, and the determining factor appears to be the duration of the active growth which takes place in the cells of the implanted carcinoma—the longer they grow the greater the tendency to sarcomatous changes in the tissues of the host. At the present time 60 mammary carcinomata are being propagated and in none can it be said that any one tumour is an exact counterpart of another. Thus we see that from the epithelial cells of one and the same organ a number of distinct forms of malignant new growths may arise and main- [illegible] ted. Again, whilst [illegible] he tumours of any [illegible] tions in structure and biological behaviour. Furthermore, the variations in histological character do not appear to be necessarily *accompanied by corresponding differences in malignancy.* Further investigations have been carried out for the purpose of discovering the manner in which animals can be rendered resistant or immune to inoculation with cancer. It has in former years been shown that this can be effected by the implantation either of normal or cancerous tissues. The later experiments have shown that if the cells introduced into the animal have had their vitality destroyed either by chemical or physical agency they are deprived of their immunising power. The action of radium on normal and cancerous cells produces a similar effect, for it is found that exposure to the emanations of radium, though for a time which is insufficient to cause any *discoverable alteration in the structure* of the cells, yet deprives them of the power of conferring resistance or immunity against inoculation by cancerous tissue. The similar action which radium has on both normal and cancerous tissue supports the opinion already expressed in 1905 that radium has no selective action on cancerous cells. All attempts to obtain an anti-cancerous serum have hitherto been unattended with success, and experiments have been made, and are still being continued, to determine, if it be possible, to separate from the cancer cells immunising powers apart from their continued growth and capability for propagation. Large numbers of mice suffering from spontaneous cancer as well as from inoculated growths have been treated by the implantation of normal or cancerous living tissues, but it is, as yet, premature to draw any conclusions as to the effect of such implantation either in conferring resistance to the growth of cancer, or in influencing its dissemination on recurrence after the removal of a cancerous tumour. It has been determined on the recommendation of the Statistical Committee to cease the collection of cases from the general hospitals of England and Scotland. 13,000 cases, which have been submitted to microscopical examination and pronounced to be cancerous, have been received, and this number is considered to be sufficient to afford data as satisfactory as would larger numbers for testing the value of "cancer censuses," and for estimating the correctness of the mortality of the disease as shown in the national mortality statistics. The collection of these cases has proved the importance of post-mortem investigation, and the difficulty which exists in the diagnosis of cancer. The collection of data from outlying portions of the Empire is being continued, and some new and interesting facts have been obtained. Reviewing the work done during the past seven years it is seen that the investigation into the nature and cause of the disease stands in a very different position now from what it did when the Fund was instituted. A large number of the hypotheses regarding the cause of cancer put before us then have been shown to be untenable, and the biological changes which living animal cells can undergo or give rise to, have been closely studied [illegible] out a fresh and hopeful field [illegible] the experimental study of ca[illegible] entailing considerable extra labour on our staff, to a large number of independent workers in cancer research both in this country and abroad. In the opinion of your committee it is by the free interchange of views and material between the independent workers in cancer research that definite results may be obtained rather than by holding formal conferences in which theories not infrequently play a more important part than facts. Until some general consensus of *opinion as to the cause and nature of* cancer has been arrived at by those who devote themselves to the research, it appears premature to hold a general conference on the question.

Sir HENRY MORRIS (honorary treasurer), in seconding the motion, said that the annual reports which had been presented were divided into two parts, the one dealing with the scientific results of the research, and the other dealing with the financial position, and it had been thought desirable, in drawing up the report this year, to draw special attention to one of those changes which came about through lapse of time, and which in this instance, was particularly regrettable, though unavoidable. He referred to the passing of the old Examination Hall, where the research work had been carried on since its initiation into new hands. It had been a great feature in favour of the Cancer Research Fund that not a single penny had been spent upon bricks and mortar or upon equipment, but he feared that the time would shortly arrive when it would be impossible to make a similar statement. Owing, however, to the fact that the Royal *Colleges had become tenants for the time being of a large* part of the Examination Hall, provision had been made for the continuance of the research work in the same quarters for the next three years. After that time it was not improbable that some demand might be made upon the capital of the Fund for the purpose of providing it with a new home. Whether that would be necessary or not he could not predict, but he felt quite sure that the subscribers and donors to the Fund might have confidence that, in the event of building becoming necessary, strict economy would be studied as well as efficiency.

The resolution was carried unanimously.

Mr. FIENNES next moved a vote of thanks to the chairman and members of the Executive Committee, the sub-committees, the honorary treasurer, and others who had assisted in the work of the Fund during the past year. He could imagine no body of gentlemen to whom the thanks of the public were more justly due. From the inception of the Fund it was evident to everyone who, with knowledge, *gave himself to the work*, that the *quest* would be long and arduous; that nature would not yield up one of her deepest and direst secrets without a prolonged struggle. It was evident also that the public, at first ardent in hope that the problem of the deadly scourge would be speedily solved, would, as year by year went by, grow forgetful, even despairing. Nevertheless, those whom he asked the meeting to thank had given their time and thought without measure and without price to a work apparently so priceless, and for that the deepest gratitude was due. The statement which had just been made—a statement full of hope and yet little calculated to attract those whose attention was continually caught by gaudy phantoms—was the measure *of the wisdom of those* who, *in the founding of the Fund*, insisted that it should be based on realised and realisable assets. The subscription list for the year showed, unfortunately, that public interest had waned; and, speaking as a layman, he would say that as soon as it was possible, without doing violence to the scientific conscience, it was important that results, even negative results, should be announced. The vote of thanks which he proposed included a number of the names best known in British medicine, and some of the most munificent of public benefactors. Without enumerating them all, perhaps he might be allowed to refer specifically to Sir Henry Morris, by whose recent advancement all who were connected with this movement felt themselves honoured. *Sir Henry Morris's claims on the gratitude of* mankind were not limited to his work in connexion with this Fund; but the record of unselfish toil which he had given to its organisation and development would ever stand as a memorial to him.

Mr. NEUMANN seconded the motion, which was unanimously agreed to.

Sir R. DOUGLAS POWELL proposed that *Professor G. Sims* Woodhead be re-elected a representative of the general committee on the Executive Committee, which was seconded by Dr. NEWSHOLME, and carried.

Mr. BUTLIN moved:

> That the Royal Colleges, having discontinued the appointment of a [illegible] College.

This was seconded by Dr. ROSE BRADFORD, and agreed to.

Sir JOHN TWEEDY, in moving a vote of thanks to the Prince of Wales for presiding, said that the leadership of His Royal Highness was of the greatest service to those who were working for the Fund and a source of particular encouragement to the medical and surgical experts who were engaged in this work and who were supervising it. Moreover, it was an assurance to the subscribers that the administration of the Fund was carried on with due regard to efficiency and economy. For more than 2000 years the best minds in the medical profession had been engaged in the study and investigation of cancer, but he had no hesitation in saying that more progress had been made in the last six or seven years—i.e., since the inception of the Fund—than in the previous 20 centuries. There was no disguising the fact that this recent progress was entirely the outcome of the experimental method, and it was in this respect he thought His Royal Highness's patronage and support was of such great service to the Fund and to the community. They could not close their eyes to the fact that there was a small but influential section of the community who disapproved altogether, and under any circumstances, of the experimental method. There was, however, a larger and a more enlightened portion of the community who were *willing that this experimental method should be continued* under the proper safeguards, not only of efficiency and skill, but of scrupulous considerations for humanity and refinement. It was in this respect that he thought His Royal Highness's distinguished support and headship of this fund was of such great service to the community. The goal at which they were aiming might be distant, but he was confident that they would only reach it by the experimental method. By any other method they not only made no real progress, but they walked merely in a circle.

Sir JOHN MCFADYEAN seconded the motion, and in doing so said he would like to associate himself with everything that had been said by Sir John Tweedy. It must be a source of satisfaction to His Royal Highness, as President of the Imperial Cancer Research Fund, to know that everything that was humanly possible was being done by Dr. Bashford and his able colleagues to throw light on the cause of a disease which was the occasion of so much human suffering as cancer; and as chairman during recent years of the Pathological Subcommittee of the Fund he wished to corroborate what had been said both by Sir William Church and Sir John Tweedy as to the considerable progress that had already been made towards the final objects of the Fund. No one who was acquainted with the scientific reports which had already been published could doubt that for a moment. In the first place, a number of erroneous theories, which were positively harmful because they were directing the research into fruitless channels, had been entirely swept away; and, in the second place, new facts of the greatest pathological interest had already been discovered. It was quite true that the cause of cancer and the means of preventing or of curing it had not been discovered, but even with regard to these points there was, he thought, no occasion to despair. At any rate, the interest which His Royal Highness was pleased to take in the Imperial Cancer Research Fund was a constant encouragement to those who had to plan and to carry out the work for which the Fund made itself responsible.

The motion was passed with acclamation.

The PRINCE OF WALES in reply said:—

Gentlemen,—I sincerely thank you for the cordial manner in which you have supported the vote of thanks so kindly proposed and seconded by Sir John Tweedy and Sir John McFadyean. Last year circumstances prevented me from attending at our annual meeting, so I am glad to be able to meet you here to-day, and, after listening to Sir William Church's remarks, I think we may congratulate ourselves upon the results of the work of the Fund in the past year. In the report of the executive committee reference is made to a petition which was presented by the International Association for Cancer Research in Berlin to His Majesty the King, during his visit to Germany. The correspondence which has taken place, and all the proceedings of the executive committee on this subject, were submitted to me, and I wish now to say that I gave my approval to the decision of the executive committee, feeling convinced that the methods adopted by the Imperial Cancer Research Fund, of freely distributing their material to workers in every country, *of permitting anyone with satisfactory credentials* to study our methods in our laboratories, and of encouraging international collaboration amongst the workers in the various cancer laboratories are the wisest and most efficient means of advancing the study of cancer. This policy of active laboratory collaboration as distinct from conferences has been productive of much good work already, because, whilst the Fund has achieved a recognition of its position as a national and imperial institution, the scientific standing of the staff and the freedom with which it accords assistance to foreign laboratories and workers are rapidly establishing for it a position of international importance. When presiding over this committee on previous occasions I have expressed the view that immediate results in regard to the cure of cancer must not be counted upon, but that rather we must look forward to steady and consistent progress in accordance with the experience of all scientific investigation. There can be no doubt, however, that the seven years' work already accomplished by the Imperial Cancer Research Fund has brought about a complete change in the standpoints from which cancer should be studied. Many and varied lines of research are being pursued with the utmost perseverance, and every development, as it occurs, is followed up with the minutest care. During the past year an important work—the Third Scientific Report—has been issued from our laboratories and *has been received with high appreciation by all* those at home and abroad who are competent to express opinions on these highly technical researches. This, of itself, marks a steady and valuable advance, and one with which we have every reason to be satisfied. The number of applicants to work under the general superintendent, coming as they do from all parts of Europe, from the United States, as well as from Japan, is evidence of the high value which is attached to the work in our laboratories. The honorary treasurer calls attention to the fact that again the expenditure has exceeded the year's receipts, and that there is now an overdraft at the bank. Looking to the possible duration of these researches, the realisation of capital is to be deplored, but this will be unavoidable unless further assistance in the shape of annual subscriptions and donations is forthcoming. In conclusion, I offer my best thanks to the chairman and members of the different committees, and also to Dr. Bashford, our director, and his colleagues for the valued services rendered by them during the past year.

The proceedings then terminated.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 16th, 1831.

EXTRAORDINARY RECOVERY OF SIGHT.

THE following case is very singular:—Pêcheur, a serjeant in the Royal Guards, received so violent an injury on the left eye by a fall, that the globe of the eye was burst, and the crystalline lens, together with the aqueous and vitreous humours, were forcibly expelled. The palpebræ were ecchymosed, the conjunctiva was red and bloated, and the lower part of the cornea was separated from its attachment to the sclerotic by an irregular cut, through which a portion of the iris protruded. The parts were washed, the iris was carefully returned, the divided edges of the cornea were approximated, the eyelids were drawn close and retained so, and a quantity of blood was drawn from the temporal artery. Ice to the head, sinapisms to the feet, constant darkness, and a rigorous diet, were enjoined. During the night a second bleeding was practised, and the next day cupping-glasses were applied to the nape and between the shoulders. Baron Larrey considered this eye as lost, or at least for ever deprived of the faculty of sight; but, "*a notre très grande et agreable surprise*," the globe gradually refilled, on the 22d day the cornea began to assume a healing aspect, and in about six weeks it was perfectly cicatrized. The natural form and almost ordinary volume of the organ were restored, and by the aid of a very convex glass this soldier came to see objects distinctly, and continues to discharge all the duties of his office. "This very curious case evidently proves, that the vitreous humour, although in greater part lost, can be regenerated," and that the crystalline lens may be dispensed with!—*Med. Chir. Rev.*

THE TREATMENT OF SARCOMA BY BACTERIAL TOXINS.

A MEETING of the Surgical Section of the Royal Society of Medicine was held on July 13th, Mr. J. WARRINGTON HAWARD being in the chair, when Dr. W. B. COLEY (surgeon to the General Memorial Hospital, New York) delivered an *address on the Treatment of Sarcoma by Bacterial Toxins*, a treatment associated with his name. He said:—

Although I have been working constantly upon this line of investigation during the past 17 years, it has grown more interesting to me with each succeeding year, and while the results have not been as satisfactory as one who is seeking for perfection could wish, they have been sufficiently real and tangible, I think, to be entitled to more careful consideration than they have yet received. Furthermore, they may have an important bearing upon the whole cancer problem, since if by the administration of certain bacterial toxins we can cause the degeneration, death, and absorption of living tumour cells of one variety of cancer—sarcoma—it is not unreasonable to suppose that by the use of some other forms of bacterial toxins we may succeed in destroying or inhibiting the growth of the other and more common variety—carcinoma.

First, I wish to emphasise the point that the method rests upon a solid foundation of accepted and indisputable clinical facts—namely, that in a considerable number of cases of inoperable cancer of all varieties, and especially sarcoma, such tumours have been known to entirely disappear under attacks of accidental erysipelas, and patients have remained well for many years thereafter. For the benefit of those who refuse to accept clinical results unless confirmed by laboratory experiments these latter tests have now been supplied, since during the last two years, at the Huntington Cancer Research Fund, Dr. Martha Tracy and Dr. S. P. Beebe have shown that large multiple sarcomas in dogs rapidly disappear under local or systemic injections with the mixed toxins of erysipelas and bacillus prodigiosus. I have already collected 38 cases of malignant tumours, 17 sarcoma, 17 carcinoma, and four doubtful, in which an attack of erysipelas had occurred. In 23 cases the attack was accidental, and in 15 it was the result of inoculation. Of the 17 cases of carcinoma, three were permanently cured. One, a probable carcinoma, was well five years after the attack of erysipelas. The remaining 13 showed more or less temporary improvement. Of the 17 cases of sarcoma, seven were well from one to seven years afterwards. There was little change in preparation until Dr. Tracy's experiments at the Huntington Fund two years ago proved the truth of the opinion that I had already expressed some time before, based upon clinical observations alone, that the bacillus prodigiosus had in itself a curative effect upon tumours, independent of any action it might have in intensifying the virulence of the erysipelas. Dr. Tracy's [illegible] experiments with sarcoma in dogs showed that sarcomas would disappear under the injections with the bacillus prodigiosus alone, without any erysipelas, although not quite so rapidly as when the combined toxins were used. Utilising [illegible] been possible before—namely, a definite standardisation of dosage. This enabled us to overcome the greatest difficulty we had had to contend with all along. The first preparations which Dr. Tracy made in the way described had so large an amount of bacillus prodigiosus that very severe reactions were obtained by minute doses, and in one case, in the hands of another physician, death resulted within a few hours after [illegible] continued up to the present time.

The macroscopic as well as microscopical changes observed by myself and others have been precisely the same as those formerly noted in cases of sarcoma treated by inoculation of the living germs. First, the tumour becomes much paler, owing to decreased vascularity; secondly, it becomes much more moveable and less fixed to the surrounding tissues; thirdly, it soon begins to show areas of softening, due to [illegible] r elements; [illegible] by absorp- [illegible] the tumour tissue. In such cases incision and drainage are sometimes advisable, provided the tumours are in accessible regions. *These changes are precisely the same, whether the toxins have* been injected directly into the tumour or whether the injections have been made in remote parts of the body, proving that the action of the toxins is systemic rather than local. In a certain number of cases—in my own experience in a little over 10 per cent.—this degenerative process has gone on until complete absorption of the tumours had taken place and the patients have remained cured. In other cases improvement is only temporary, and in a very few instances, especially in cases of very large and vascular tumours, particularly in those of the melanotic type which of late pathologists are inclined to class as carcinoma, no marked beneficial effects have been noted. What is the explanation for these variable results?

The explanation is, I think, not so very difficult. My own belief, expressed 16 years ago and held more firmly with increasing clinical experience, is that all varieties of malignant tumours are of extrinsic or microbic origin. Just what type of organism this may be, whether bacterium, protozoon or spirochæta, or what not, is of little consequence. Assuming such origin, we have but to follow the analogy of other diseases of known germ origin. We know that in all such diseases there is a natural immunity and an acquired immunity. In the case of malignant tumours there is probably a natural immunity which is very great, but in certain cases it is absent or becomes lowered and the germ finds a favourable site and here starts the primary malignant tumour. The important rôle that trauma or injury plays in the development of malignant tumours can, *to my mind, be explained only on the theory of a* microbic origin. Assuming such an origin, the action of the toxins appears to me to produce certain changes in the blood of the sarcomatous patient which restore the weakened or lost immunity, or natural resisting power of the tissues, when the cancer cell, no longer finding conditions favourable for further growth and development, undergoes a process of degeneration or absorption. The reason why a cure results in some cases is, that in these the antagonistic action of the toxins is sufficient to destroy the cancer cell completely or render the soil unfavourable for further growth, whereas, in other cases, the tumour cells, by reason of greater vigour or better nourishment, are more resisting, and although receiving a temporary set-back by reason of the changes in the blood produced by the toxins, soon accommodate themselves to the new environment and continue to grow as before. The high temperature produced by the toxins may also be a factor in causing the improvement that follows their use. Many and repeated blood examinations of sarcomatous fractures treated with the toxins show almost universally a marked leucocytosis as a result of the treatment.

While in my earlier papers I have practically limited the use of the toxins to cases of inoperable sarcoma, further experience has convinced me that they have a much wider field of usefulness. I would at present advocate their use first in all cases of inoperable sarcoma, except the melanotic, which are classed as epithelial in origin by most pathologists; secondly, in cases of sarcoma originating in the long bones in which operation means a sacrifice of the limb (in these cases if no improvement is noted at the end of two or three weeks, I would then advise excision, resection, or amputation, according to the individual case); thirdly, in all cases of operation for primary sarcoma upon the healing of the wound (as a prophylactic against recurrence); and fourthly, after all operations for carcinoma. In the last instance the proceeding would greatly lessen the number of recurrences, an opinion which is based partly on the clinical observations of a considerable number of cases in which both epithelioma and carcinoma have entirely disappeared and have been permanently cured from attacks of accidental erysipelas. By far the greatest value of the toxins in my opinion lies in this use as a prophylactic measure. Used in this way, in much smaller doses than would be given in large inoperable tumours, they are practically free from risk. I have already a sufficient number of cases of sarcoma in which I have used the toxins as a prophylactic measure to justify such use. The use of the toxins as a prophylactic after operation I believe to offer by far the most important field of all, and one that is gradually being appreciated by the profession. At the Mount Sinai Hospital the toxins are now used in all inoperable cases of sarcoma as well as after operation for primary sarcoma. In carcinoma I believe the toxins, if used after operation, will prevent in a considerable number of cases recurrence that would otherwise take place. When used as a prophylactic measure in the way I have indicated, I believe the toxins to be entirely devoid of risk. There have been no deaths in the cases in which the treatment was used as a prophylactic. In these cases the dose given is smaller and it is not increased to the point of producing severe reactions; a moderate temperature of 99° to 101° is all that is required. This will not in any way interfere with the ordinary routine of life. The toxins can be given for long periods of time without any harmful effects, as is shown by a case of eight times recurrent sarcoma of the chest wall in which the treatment was continued for four years, and the patient is now well 14 years after the beginning of the treatment, or ten years after its cessation.

The facts I have set forth are sufficient in my judgment to justify the giving up of the traditional method of treating all cases of sarcoma of the long bones by immediate amputation. In most cases I believe it safe to wait for two to three weeks, the time required for a trial with the toxins, before sacrificing the limb. Cases of sarcoma of extremely rapid growth will probably show little or no effect from the toxins, and it will be natural to say that valuable time will be lost by the preliminary use of the toxins. However, it is my opinion that early operation in these cases is not of the slightest avail. On the other hand, in certain cases—probably a small number—the limb will be saved by the preliminary use of the toxins. In those in which early improvement is not marked operation can then be performed with even greater chances of ultimate success than had the toxins not been first used. The greatest value of the toxins in sarcoma of the long bones will, I believe, be shown to lie in a judicious combination with conservative operative treatment. By such procedure a hip-joint amputation, which has been the almost uniform rule for sarcoma of the femur, will give place to an amputation below the trochanter, a stump of sufficient length being left to permit the wearing of an artificial limb. The toxins will be administered for a considerable period of time after amputation with the hope of destroying the cells which were left behind and which, with operative treatment alone, cause the local and metastatic recurrences. The same rules apply to sarcoma of the humerus. In sarcoma of the tibia, fibula, and radius and ulna, particularly of the myeloid type, in place of amputation, as formerly advised and still advocated by the great majority of surgeons, we can safely substitute either curetting or partial resection, followed by a thorough course of the mixed toxins. While good results have been obtained in a very limited number of cases in this group by operation alone, I am convinced that that the number of successes will be greatly increased by combining the toxin treatment with conservative operation. Earlier diagnosis is steadily becoming the rule, owing to increased knowledge of the pathology, coupled with more correct interpretation of X-ray plates and the use of earlier exploratory operations; and conservative treatment along the lines I have mentioned will soon show results infinitely superior to those obtained by radical operations.

It is very hard to lay down any definite rules as to the duration of treatment such as would apply to all cases. My own feeling, based upon experience up to the present date, is that there is much more danger in stopping the toxins too soon than in administering them for too long. With four or five exceptions, cases in which the tumours have disappeared under the toxins have remained well. These few cases of recurrence furnished the most convincing evidence of the undoubted influence of the toxins in sarcoma, inasmuch as they absolutely prove that, in these cases at least, there could have been no error of diagnosis. Can we then form any practical rules to guide us as to how long the toxins should be administered? I would say give the toxins till the tumours have entirely disappeared and then continue in smaller doses and at longer intervals for three or four months longer. If no improvement is noted at the end of four or five weeks a successful result is not likely to occur and retardation of the growth is all that can be expected from a further use of the toxins. Much depends upon a judicious determination of the dosage for the given case. I always begin with one-fourth of a minim, diluted with sufficient boiled water to ensure accuracy of dosage, injected either into the buttocks or pectoral region. After the individual's susceptibility has been ascertained one can then inject into the tumour itself if it is in an accessible region. The initial dose into the tumour should always be less than, not more than one-fourth of, that used elsewhere. I believe it a good plan to give the injections alternately into the tumour and into the buttocks. Daily injections should be given, increasing by one-fourth of a minim until the desired reaction—namely, a temperature of 102° to 104°—has been obtained, unless the patient is in a weakened condition. Having secured this reaction, the dose should no longer be increased until it fails to give a reaction, when it can again be increased by one-fourth to half a minim.

The greatest obstacles to a fair trial of the toxins up to the present time have been: (1) the difficulty of obtaining a preparation of the toxins of uniform standard of strength and efficiency; (2) the published failures of a few men who have given the method a limited and most imperfect trial, usually with the preparation of the toxins entirely different from that used by myself; and (3) the limited number of cases of inoperable sarcoma seen by the ordinary physician or surgeon. Occasionally the physician has heard of the mixed toxins in such cases, but if he has read of the method he has probably forgotten the details and has little faith in its value. Now and then a surgeon is found who takes the time to give the matter special thought, and who is willing to give the patient the benefit of a trial with the toxins. He begins with some fears and more doubts, and when he sees the patient in one of the severe chills, sometimes with marked cyanosis, very rapid and feeble heart action, with a temperature of 103° to 105°, he hesitates to go on, or is unable to instil into the patient the courage and confidence so necessary to the continuation of the treatment to a successful termination. For these or other reasons injections are stopped and the treatment is pronounced a failure. While I have personally found the administration of the mixed toxins practically free from danger, there have been several fatal cases in the hands of other physicians brought to my notice which, taken together, show that there are certain risks connected with the treatment. If, however, the precautions which I have always carefully emphasised in former papers be observed, these risks, I believe, will be reduced to a minimum.

In my own experience, in nearly 500 cases, there have been only three deaths. In the majority of the fatal cases thus far observed death was apparently due to an embolism. This was the cause in two of my own cases and in both instances the general condition of the patients was extremely bad; there was generalisation of the disease and very marked involvement of the mediastinal glands. In both cases the patients had only very small doses of the toxins which were not pushed to the point of giving any marked reactions. Most of the deaths in the hands of other men have been due, I believe, to too large an initial dose given directly into a vascular primary growth. In recent years I no longer inject the initial dose directly into a tumour, but first test the individual susceptibility of the patient by systemic injections in the buttocks or pectoral region; after a few such injections local treatment may be begun, always starting with a minimum dose. I rarely give more than 1-6th cubic millimetre into the tumour in children, especially if situated in the neck or mediastinum, and never more than 1-4th cubic millimetre in adults. I have seen a temperature of 105° result from 1-5th cubic millimetre injected into a large cervical tumour in a child. In one of the fatal cases in the hands of other men, death resulted from an injection of 1-4th cubic millimetre of Dr. Tracy's early preparation (twice as strong as at present) directly into a mediastinal tumour. This was an elderly woman of very feeble vitality. Another case, recently brought to my notice by the physician in charge, contains an important lesson—i.e., that the toxins should never be administered by any physician who is not willing to give sufficient time—I will not say to read thoroughly all of the literature connected with the treatment, but at least the directions upon the bottle. In this case the initial dose was five cubic millimetres injected into a vascular tumour. The physician stated that he had turned the case over to his assistant who gave him five cubic millimetres and the patient died in 15 minutes. Death might also have resulted had he given him 20 grains of morphine, though perhaps not so quickly. The toxins are indeed, like strychnine and morphine, safe if judiciously and intelligently administered, but exceedingly dangerous if given in the way described.

I have known of another instance, a case of sarcoma of the lower jaw, in which, after two operations had been performed and it was not thought that the disease had been entirely removed, the toxins were advised immediately after operation. In this case also the treatment was turned over to an assistant. Although never within the last 15 years have the directions sent out with the toxins called for larger initial doses than a quarter or half of a cubic millimetre, the assistant in this instance proceeded to give 20 cubic millimetres as a first dose. This was some years ago when the preparation was considerably weaker than at present, or at least when its strength was more variable. Although the patient went into coma and remained comatose and delirious for some time, he finally recovered and is well now, two years afterwards, the tumour of the jaw having been cured.

In a few other cases, however, in which death resulted the ordinary precautions had apparently been carried out. One such case was seen by myself in consultation and the treatment advised and a general outline of the dosage given. This was a woman, 55 years of age, with a very large vascular sarcoma of the ilium. Her general vitality was much impaired and the circulation was not good. The toxins were begun in minute doses, 1-4th cubic millimetre, and gradually increased up to the point of reaching a temperature of 103° to 104°. After about two weeks' treatment an injection of 12 cubic millimetres caused a severe chill, the patient became very weak and exhausted, and did not recover. In this case, had I had personal charge of it, I have no doubt that, seeing that she did not bear the toxins well and that *the temperature remained high*, I should not have increased the dose as rapidly as was done. It is natural that any new method of treatment of disease should stand a certain definite test before it can hope to secure recognition. When it comes to the consideration of a new method of treatment for malignant tumours we must not wonder that a profession, with memories overburdened with a thousand-and-one much vaunted remedies that have been tried and failed, takes little interest in any new method and shows less inclination to examine into its merits. Cold indifference is all it can expect, and rightly, too, until it has something beside novelty to offer in its favour. 16 years ago, when I began to use the toxins for inoperable sarcoma, I did not expect the profession to adopt the method. I fully expected to wait until its great objection of novelty had given way to time and my own results had been duplicated and confirmed by other observers. No one could see the results which I saw and lose faith in the method. To see poor, hopeless sufferers in the last stages of inoperable sarcoma show signs of improvement, to watch their tumours steadily disappear, and finally see them restored to life and health was sufficient to keep up my enthusiasm. That only a few instead of the majority were followed by such brilliant results did not cause me to abandon the metho[illegible] more earnest search for further [illegible] now obtained, comprising 52 [illegible] that number in the hands of otl[illegible] I believe, to convince [illegible] toxin treatment of inc[illegible] sufficient value to be [illegible]

Mr. H. T. BUTLIN [illegible] Surgeons of England), in moving a vote of thanks to Dr. Coley, said that if America could spare Dr. Coley for one year this country would be glad to have his services.

Sir A. E. WRIGHT, who seconded, suggested that in order to raise the treatment carried out by Dr. Coley above the reproach of being founded only on clinical experience an enormous amount of laboratory work was required to supplement their knowledge. What was wanted was some method by means of which the dosage could be known [illegible] had not [illegible] ory side [illegible]

The CHAIRMAN said that they hoped to have some satisfactory basis for the use of the toxins, and that what Dr. Coley had said would encourage them to try the method in a disease which otherwise was so hopeless.

The vote of thanks was carried with acclamation, and Dr. COLEY in a few words acknowledged the honour. He pointed out that his method was absolutely scientific and was based on laboratory experiments.

THE NOTIFICATION OF TUBERCULOSIS IN IRELAND.

THE Tuberculosis Preventi[illegible] the Royal assent on Dec. 21 [illegible] of opposition in its passage [illegible] siderably modified in the p[illegible] of the measure had reference to the notification of tuberculosis. The Government wished this to be compulsory throughout Ireland, but in order that the Bill might pass it was found necessary to introduce a clause permitting local authorities to decide whether notification should be put in force within their areas. The first clause of the Act, being the portion of most interest to the medical profession, was printed in THE LANCET of Dec. 26th, p. 1946. One of its requirements is that the Local Government Board for Ireland shall make regulations for carrying into effect the provisions of this section. The Board has accordingly issued two orders which have been recently published in the *Dublin Gazette*, came into force on July 1st, and are designated respectively "The Tuberculosis (Conditions of Notification) (Ireland) Order, 1909," and "The Tuberculosis Regulations (Ireland) Order, 1909." The first portion of the following quotations is taken from an accompanying "Memorandum on the Objects of the Act" also issued by the Board.

The main aim and object of the Act and of the regulations made under it is to place further power in the hands of local authorities for preventing the spread of tuberculosis. Part I. of the Act deals with the notification of tuberculosis and disinfection of premises used by tuberculous patients [illegible] It was the desire [illegible] compulsory [illegible] unnecessary [illegible] patible with [illegible] as applicable [illegible] Act have not been extended to tuberculosis, and there is no power given to [illegible]

[illegible] same [illegible] loyed [illegible] r any [illegible] edical [illegible] with [illegible]

[illegible] any ...... [illegible] to prevent or check the spread of tuberculosis. ...... The sanitary

> authority, or the medical officer of health acting under a formal authorisation, may require the delivery of infected articles ...... for disinfection. ...... Compensation for u[illegible] process of disinfection may be paid. [illegible] mmodation shall be provided free of c[illegible] ...... [illegible]mpelled to leave their dwelling while disinfection is being carried out. ...... A penalty not exceeding £5 is imposed for obstructing a duly authorised officer ...... in carrying out ...... disinfection, and the officers are given a right of entry. ......
>
> *Hospitals and dispensaries.*—Part II. of the Act ...... deals with the provision by the council of any county (including the town council of a county borough), of hospitals, sanatoriums, and dispensaries for the treatment of the inhabitants of their county or county borough suffering from tuberculosis ....
>
> *Miscellaneous provisions.*—Part III. of the Act ...... contains provisions intended to deal with the prevention of tuberculosis. Sanitary authorities ...... may arrange for public lectures and for the distribution of literature on subjects relating to tuberculosis, and they may provide drugs and appliances, for example, spitting flasks. ...... Power is given to county councils to appoint a bacteriologist, being a medical practitioner, for the examination of meat or milk or milk products, and of sputum or pathological specimens. ...... In any county in which a bacteriologist has been appointed power is given to any medical officer of health ...... to take samples of milk or milk products for examination or analysis. ...... Penalties for obstruction are imposed, amounting in the case of a first offence to £20. ...... Where a veterinary surgeon certifies any milch cow to be affected with tubercular disease of the udder the sanitary authority may cause the animal to be slaughtered and may pay the owner compensation, the amount of which ...... shall not in any case exceed £10. The carcase ...... shall be ...... disposed of as the circumstances require. ......

It is not our purpose on the present occasion to make any detailed reference to the Act as a legislative measure, but merely to mention some obvious features of the instructions issued by the Local Government Board for Ireland in its Memorandum and Orders. Speaking generally, and keeping in mind the Parliamentary exigencies already mentioned, we believe that the Board has been actuated by an earnest desire to make the new legislation acceptable to the public. This is essential, for, as we have often remarked, no scheme for the prevention of epidemic disease can be permanently successful without the intelligent coöperation of a considerable section of the community. On the other hand, we think that the instructions are highly unsatisfactory from the medical point of view, and that there is good reason for the misgivings expressed by our Dublin correspondent in THE LANCET of July 10th. In each of the Orders a paragraph is quoted from the Act in the following terms:—

> If any medical practitioner attending on any person within any district to which Part I. of the Act extends becomes aware that that person is suffering in any prescribed circumstances from tuberculosis of any prescribed form or at any prescribed stage, the medical practitioner shall within seven days after he becomes aware of the fact send to the medical officer of health a certificate in the prescribed form and containing the prescribed particulars.

Definitions of the prescribed circumstances, form, and stage will be found in the preceding quotations from the Memorandum. Let us assume that a patient of the wage-earning class, such as a shop assistant, a clerk, an artisan, or a laundry ironer, comes to a surgery complaining of cough, expectoration, and loss of appetite, but nevertheless in full employment. The clinical history and the physical signs of pulmonary tuberculosis may be so obvious that there would be no difficulty in certifying the sputum to be infectious without bacteriological tests, but the medical practitioner is placed in the dilemma that the patient probably works in association with healthy persons and is therefore presumably notifiable. Inquiries concerning his fellow workers and previous medical advisers would arouse the patient's suspicions and trustworthy answers could not always be expected. If the practitioner fails to notify a case he takes the risk of being prosecuted and fined £2. If he is informed that the patient's fellow workers are healthy he perceives that the case is notifiable according to the statute, but he feels that in sending a statutory notification to the proper quarter he is taking the risk of receiving no fee because the sanitary authority may in reply inform him that the case has been notified already. If the patient is, or claims to be, married the case is notifiable when the partner is healthy, but not so when the partner is tuberculous. How is the practitioner to ascertain this without an examination of the other individual, who probably does not want to be examined and has no intention of paying a fee? The inconsistencies and difficulties of the practitioner's position are so obvious that there is no need of further examples. In short, it would be amply sufficient to ask the practitioner to notify the patient's name and address, together with a certificate that he suffers from tuberculosis in an infective stage, leaving the question of "prescribed circumstances" to be investigated by the officials of the sanitary authority.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on July 8th, the President, Sir HENRY MORRIS, Bart., being in the chair.

The PRESIDENT reported the result of the annual election of members of Council, as already reported in THE LANCET, and Sir W. Watson Cheyne, Mr. R. Clement Lucas, and Mr. Harrison Cripps were introduced, and, having made declarations in the terms of the oath prescribed by the Charter of 1800, took their seats in the Council.

A report was received from the museum committee with reference to the revision of the pathological catalogue, and the recommendations of the committee were approved; these included, among others, the appointment of a pathological assistant in the museum and the appointment of a expert to advise as to the gynæcological specimens. Th best thanks of the Council were given to the authorities o the Egypt Exploration Fund for their valuable gift of 8 skulls of the Sixth Dynasty, recently found at Abydos i Egypt.

An address was read, which had been presented by th President, on behalf of the College, to the chancellor, masters and scholars of the University of Cambridge on the occasio of the commemoration of the centenary of Charles Darwin birth. The best thanks of the Council were given to th President for preparing the address.

The following lecturers were appointed for the ensuin year:—Hunterian professors: Dr. Arthur Keith, four lecture on the Anatomy of the Negro and Negroid Races; Mr. W. Handley, two lectures on the Surgery of the Lymphati System; Mr. George Coats, two lectures on Congenital Abno malities of the Eye; Dr. R. Horace Paramore, two lectures o the Functions of the Pelvic Floor Musculature; and Dr. Bolton, two lectures on the Pathology of Gastric Ulce Arris and Gale lecturers: Mr. Sydney R. Scott, one lectu on the Physiology of the Human Labyrinth; and Dr. Pet Thompson, two lectures on the Erect Attitude, its Adoptio Maintenance, and Failures, with Especial Reference Certain Surgical Conditions. Erasmus Wilson lecture Mr. Samuel G. Shattock, six demonstrations on Surgic Pathology. Arnott demonstrator: Dr. Arthur Keith, s demonstrations of the Contents of the Museum.

Mr. H. T. Butlin was unanimously elected President, a Mr. Pearce A. Gould and Mr. Clement Lucas were appoint Vice-Presidents.

The next meeting of the Council will be held on Thursda July 29th.

MEDICINE AND THE LAW.

More about the Workmen's Compensation Act, 1906.

IN a recent letter to our columns[1] Mr. Albert Bentha made the recommendation that when an accident has incapa citated a workman it is in the interest of the employer to pa the half wages required by the Workmen's Compensatio Act with promptitude, and also to see that the workman receiving proper medical attention and nursing, as this wi in many cases shorten the period of invalidism. This soun advice might be taken notice of by insurance companies, wh presumably are usually responsible for the attitude adopte by the employer, and would be applicable to cases whe there is no doubt as to the liability to compensate. Th suggestion as to medical attention and nursing might ofte prove valuable in instances where the workman is honestl anxious to get well, but a substantial number of case under the Workmen's Compensation Act have unavoidabl formed the subject of legal intervention and one poin seems to have been elicited with frequency—namely, tha the injured man, supposing that he is injured, is no necessarily in a hurry to be declared sound again. It has however, been more often the liability of the employer compensate which has formed the subject of repeated argu ment than any question as to the duration and extent of th injuries.

The case of Craske *v.* Wigan, which was recently made th subject of an appeal before the Master of the Rolls, Lord Justice Buckley, and Lord Justice Kennedy, from the award of the Gloucester county court judge, is worth recording briefly for medical readers. The applicant for compensation was a ladies' maid, who one evening sat sewing by an open window with an electric lamp near her. While she was so engaged a cockchafer flew into the room and in endeavouring to repel it as it hovered round her head she struck herself a blow with her knuckle in the right eye, inflicting injuries which resulted in her losing her sight in the organ. It is stated in one report which we have seen of this case that the work which the maid was engaged upon was not her mistress's but her own; the Court of Appeal does not, however, seem to have laid any stress on this, but in a judgment which distinguished the case from Andrew *v.* Failsworth (1904, 2 K.B. 32), Challis *v.* London and South-Western Railway Company (1905, 2 K.B. 154), and Rowlandson *v.* Wright (24 Times Law Reports, 852) decided against the claimant. The court held that it had to apply the words "arising out of" the employment to the accident, and not only the words "in the course of." It must be proved that the accident arose because of something that the workman was doing in the course of his work or because his work placed him in a position of peculiar danger, otherwise the accident would not be one "arising out of" the employment. The case is interesting because it lays down decisively the principle to be applied and it also illustrates the unlikely and unpreventable occurrences for which an employer has been asked to pay compensation under the Act. In another recent case (Charles *v.* Walker Limited) the facts surrounding the workman's death may usefully be noted. He had suffered injuries which necessitated the amputation of the index finger of his left hand, and just as he was recovering from the anæsthetic after this had been successfully carried out those operating decided to remove a tooth of which he had complained. A further anæsthetic was administered, the attempt to remove the tooth was unsuccessful, and the patient was removed to the ward and there died. The county court judge, in deciding on the claim of the widow that the death was the result of the accident found that it was at least as probable that it resulted solely from a spasm induced by an attempt to swallow blood oozing into the mouth owing to the second operation, as that it was due to the anæsthetic administered for the first operation, and that the claimant must consequently fail as she had to prove her case and had not done so. The Court of Appeal upheld this decision, being of the opinion that the county court judge had "rightly directed himself"—i.e., that he had rightly applied the legal principles which it would have been his duty to explain to a jury if there had been one to assist him in such a case. The Master of the Rolls concluded his judgment by saying that the county court judge was not satisfied, nor was he, that death resulted from the operation for the removal of the finger, and the widow had "failed to discharge the onus which lay upon her of proving this fact." In a third case (Ystradowen Colliery Company *v.* Griffiths) the workman, a collier, met with an accident which injured his knee. Owing to this injury he took more than two hours to reach his home, a distance of a mile and a quarter, on a cold day, with the result that he contracted pneumonia, and when he made his claim was incapacitated from work by bronchitis and chronic asthma. The county court judge had held that this was not the natural result of the accident, and that consequently the employers were not liable to pay full compensation. But the Court of Appeal held that this was wrong and remitted the case to the county court judge, saying for his guidance, in accordance with the case of Dunham *v.* Clare (1902, 2 K.B. 292), that the principle governing the matter was not what might be the reasonable, or probable, or natural result of the accident, but whether, in fact, the condition complained of was due to it. In the instance before them the county court judge must consider whether the workman's condition was a result of the accident in the sense that it was occasioned by the debilitated condition of the man immediately after the accident. This case should warn employers as to the desirability of giving prompt aid to their workpeople when it is possible to do so after accidents for which they may be liable, and it adds force to the suggestion of Mr. Benthall quoted above. A decision upon somewhat similar lines, in which an insurance company was held liable as for an accident where death from pneumonia followed a hunting fall, was reviewed in THE LANCET of Feb. 27th, p. 642. In another recent appeal under the Workmen's Compensation Act the claim was based upon lead-poisoning contracted by a seaman when engaged in painting on board his ship at sea. The county court judge refused compensation and the Court of Appeal upheld this decision upon the construction of the Act, which admittedly would have rendered the employers liable as for an accident if the lead-poisoning had been contracted in a factory or elsewhere ashore, and if the conditions of the Act with regard to certification by the factory surgeon of the district had been complied with. It was held, however, that the Act only contemplated and provided machinery for industrial diseases contracted where there was a district with a factory surgeon to certify when they occurred, and that, whether intentionally or not, seamen at sea had been omitted from the benefits of the section bearing upon the subject (Section 8). The Master of the Rolls observed in his judgment that it was "impossible to read this section without holding that it did not apply to the case of a seaman."

---

[1] THE LANCET, May 29th, p. 1555.

Dentistry by the Unqualified.

After more than one adjournment Mr. Garrett, sitting at the South-Western police-court, dismissed the summonses against two defendants, Oscar Farkasch and Joseph Leo Rosenscheim of "the London Hygienic Institute," under the Dentists Act alleging the use of descriptions in the conduct of their business implying that they were specially qualified to practise dentistry. At a previous hearing another Rosenscheim had been dismissed from the case owing to lack of evidence connecting him with the charges. A fourth man, Newman by name, was held to have made a representation which brought him within the Act, and was fined £5, with £5 5*s.* costs. The case was dismissed as far as it concerned the principals in a business (in which the person fined was employed by them) apparently on the grounds that the skill in dentistry which they advertised was not puffed in terms which professed qualifications of a registrable character. The learned magistrate expressed the view that any man was allowed by law to extract teeth; that if he chose to say that he extracted them well he was again within his rights; and that the defendants had vaunted their skill in this manner but without going so far as to claim special qualification within the meaning of the Act. In these circumstances the comment which suggests itself is that the policy of the Dentists Act, in which it resembles the Medical Acts, is ostensibly to confer a limited amount of protection upon those whose names are on the Dental Register, and to afford means to the more educated classes of the community of distinguishing between qualified and unqualified persons. For the less educated and intelligent section of the public it provides no protection whatever, either ostensibly or in fact, leaving them to the mercy of anyone who has the commercial energy to advertise, combined with the physical strength necessary for the extraction of teeth.

Mr. Brighouse and the Town Council of Warrington.

Mr. S. Brighouse, coroner for South-West Lancashire, recently selected the conclusion of an inquest at Warrington as an occasion for making public a correspondence which has passed between him and Dr. J. C. Hibbert, medical officer of health of Warrington, and for commenting upon it. The statement was made while the jury, assembled for the purpose of an inquest which had been concluded, were signing their verdict and had nothing to do with the matter before the court, the coroner apparently desiring to obtain in this manner for his opinions the publicity conferred by a report in the local newspapers. Mr. Brighouse began by stating that Dr. G. W. Joseph, a member of the Warrington town council, had called attention, in a discussion upon the report of the medical officer of health of the town, to the infantile death-rate and to the high percentage of uncertified deaths at Warrington. Dr. Joseph had referred to the certainty of an inquest being held as a deterrent to people who might otherwise be guilty of criminal neglect of their children, and had [illegible] eparate coroner for Warr [illegible] oner for the district (Mr. I [illegible] exercised his jurisdictic [illegible] in criticising these views, [illegible] oner for Warrington would cost the ratepayers more than the existing system, and observed that he was speaking to the ratepayers by the courtesy of the jury, to whom in form his remarks were addressed. He then proceeded to read and criticise an extract from an annotation which appeared in THE LANCET of Sept. 5th, 1908, p. 748, in which attention was called to the high percentage of uncertified deaths in certain towns, among which Warrington was specially mentioned. In that article, which was based upon the Registrar-General's returns for the first half of 1908, the proportion of cases in which there was no certificate to the total of deaths registered was given as 6·3 per cent. in Warrington, as contrasted with an average of 1·4 per cent. in England and Wales and an average of less than 1·0 per cent. in the 76 large towns, among which Warrington was included. Mr. Brighouse then read a letter received by him from Dr. Hibbert, referring to the article in THE LANCET and stating that the attention of the health committee had been called to the matter. From this letter the following passage may be quoted: "The only reason I can ascertain for this high figure is the small percentage of inquests held on deaths uncertified by a doctor." Mr. Brighouse had replied in a letter which he also read. It began with a disquisition upon the duties of a coroner as defined by Section 3 of the Coroners Act, 1887, and went on to indicate the practice followed by him in these terms: "In 15 of these cases (18 deaths reported by the Warrington police in three months and upon which no inquests were held) a medical officer conversant with the case had been sent by the police and had expressed an opinion as to the cause of death which enabled me to dispense with an inquest. If in the face of these expressions of opinions by medical men I had held inquests I should have been intruding without adequate cause upon the privacy of a family in distress. In one of the remaining three cases the lady sanitary inspector of the Warrington corporation, together with the midwife, was present at the death of the child. ...... In the remaining two cases the police reports conveyed sufficient information to me to enable me to come to the conclusion that the deaths were from natural causes." The letter containing this passage concluded with the suggestion that "if the writer in THE LANCET proposes that in every case where a medical man is unable to certify as to the cause of death there should be an inquest held by me, then it will follow that there must be a post-mortem examination, and he had better place himself in communication with the county council of Lancashire and then come and sit with me when I hold unnecessary inquests and hear what the relatives have to say in the matter. The Coroners Act of 1887 has to be construed in a common-sense way, and I trust that I carry out the duties attaching to my office so as to comply with the Act of Parliament and at the same time not to wound the feelings of those who are in sorrow and distress." Another letter, also written by Mr. Brighouse to the medical officer of health, was then read. It contained as a typical instance of an uncertified death not made the subject of an inquest by the coroner the case of the wife of a member of the Warrington town council who, having been long in delicate health and under the care of a medical practitioner, died when an interval of six months had elapsed since her medical attendant had last visited her. Such a case is so obviously not typical of those under discussion that no comment is needed; but the letter concludes with another appeal of a similar character to those already quoted: "What does THE LANCET think I ought to do under these circumstances—intrude into the privacy and sorrow of the family, order a post mortem and hold an inquest? Whatever THE LANCET may say I am not going to do it, and if I so acted under the circumstances above described I do not think I should stand well in the eyes of your town council." After reading a letter in reply from Dr. Hibbert, Mr. Brighouse concluded his address with a peroration in which he referred once more to his reluctance "to intrude into the privacy of families in the midst of their sorrows."

In commenting upon these remarkable utterances of a coroner we can do no better than again quote Dr. Hibbert, who wrote: "The main point, I think, which has exercised the minds of the health committee of Warrington is why the percentage of uncertified deaths in this borough should be so much higher than in most other districts. *Is it to be inferred that coroners elsewhere unduly intrude without cause on the privacy of families in distress, and that in other districts inquests are* held where a doctor, although not able to certify the cause of death, can nevertheless express an informal opinion as to its cause? I must say that as medical officer of health I have felt that the more frequent holding of inquests, especially in connexion with the deaths of infants, the causes of which are uncertified by a doctor, would tend to make careless parents more prompt in calling in a doctor to an ailing child and more careful about its feeding and general welfare." This puts the case against Mr. Brighouse's system quite clearly, and we note that he gave no information as to the proportion of infantile deaths among the 18 uncertified cases in which during three months he decided not to hold any inquest. The nature of the system under which he obtained through medical men the information necessary to enable him to form an opinion in 15 instances we do not know, nor do we understand how medical men could make sufficiently exhaustive inquiries to enable such a conclusion to be correctly arrived at in all cases without considerable intrusion upon the privacy of any families involved. Whence they derived authority to make such inquiries and whether they in fact made them we cannot discuss from the information upon the subject contained in Mr. Brighouse's speech. At this juncture the point for the attention of the Warrington town council is one worthy of their consideration, and we are glad to see that, having the reputation of their town at stake, they are weighing it seriously. It is, as Dr. Hibbert puts it, whether the coroner for South-West Lancashire is right and practically all the other coroners in England and Wales are wrong in their methods, and whether an appreciable amount of infant mortality (and a great deal of infant suffering not ending fatally) might be prevented by the strong probability of a stringent inquiry following when a child dies after receiving no medical attention. We are perfectly well acquainted with the provisions of the Coroners Act, 1887, Section III. They are not incapable of amendment and improvement, but the words "Where ...... there is reasonable cause to suspect" that the deceased "has died a violent or unnatural death or has died a sudden death of which the cause is unknown" are sufficiently wide to allow of an inquest being held in cases in which the immediate cause of death is natural and not obscure, but in which contributing causes of neglect or wanton exposure to risk may render inquiry very desirable. Such inquiry is likely to reveal or to disprove the existence of culpable conduct on the part of persons responsible when before an inquest there is only "reasonable cause" to suspect it, and few are likely to blame a coroner who is suspicious on such occasions. Mr. Brighouse thinks otherwise, but his appeals for the approval of those into whose family sorrow and privacy he does not wish to intrude carry their own condemnation. The Warrington town council can probably estimate the amount of family sorrow and privacy that would be outraged in such cases as the 18 to which he refers, and will no doubt be of the opinion that the functions of a coroner should be exercised tactfully and sympathetically but without regard for the praise or obloquy of the general public.

THE ROYAL BUCKINGHAMSHIRE HOSPITAL.—On July 3rd Sir Frederick Treves, accompanied by Lady Treves, paid a visit to the Royal Buckinghamshire Hospital at Aylesbury. Sir Frederick Treves, who has taken great interest in the planning of the recently completed extension of this hospital, was met at the door of the institution by the chairman of the board of governors, Mr. George Carrington, and the medical staff of the hospital. Sir Frederick Treves, after inspecting the new wing, congratulated the board of management upon the possession of a hospital completely equipped in accordance with the requirements of modern medicine and surgery. In appealing for financial support—£1800 is required to free the hospital from debt—Sir Frederick Treves pointed out that a properly equipped hospital was necessary in order that physicians and surgeons might retain their skill and ability. For this reason the rich benefited from the existence of a hospital quite as much as the poor. "If," said the speaker, "I hear anyone say, 'I decline to support hospitals as they are only for the benefit of the poor, whom I support in other ways,' I tell him to support a hospital for the benefit of the rich by keeping up the standard of medical and surgical science in the district."

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Leicester Borough.—The population of this borough was estimated in the middle of 1908 at 240,172, but Dr. C. Killick Millard thinks that this figure is too high if the basis of the number of inhabited houses be employed for the computation; he puts the population at 226,200. All the rates are, however, calculated on the Registrar-General's estimate. At the beginning of the nineteenth century the people of Leicester numbered only 17,005, and in 1851 only 60,584. In 1891 the borough boundaries were extended. The marriage rate has shown minor fluctuations but generally a steady decline; but in 1908, for the first time for six years, the births have shown no decrease. The death-rate, which in 1872–76 was 25·18 per 1000, was in 1908 under 13, and Dr. Millard, in claiming a large share in such reduction for preventive medicine, observes that, although during the past 33 years there have been six medical officers of health, the same chairman (Alderman Windley) has for the whole of this period presided over the sanitary committee. Amongst the improvements brought about in Leicester is to be included the reduction which has taken place in infantile mortality, which in 1892–96 was 194·4 per 1000 births, and which is now about 130 per 1000 births. But this mortality amongst illegitimate births is still sufficiently appalling—for 1905–08 no less than 357. The new Vaccination Act has not been without its influence even in Leicester. The number of vaccinations during 1908 decreased by 40 per cent., and the exemptions granted increased by 91 per cent. Enteric fever has undergone a marked decrease in Leicester during recent years, there having been only 48 cases with eight deaths in 1908. Dr. Millard points out that there has been a marked decline in the prevalence of this disease in the country as a whole, but that there are now few towns which have a lower death-rate than Leicester—i.e., 0·33 per 10,000. The remarkable reduction which has taken place is ascribed largely to the abolition of the Leicester pail closets, and Dr. Millard draws attention to the difference which obtains in enteric fever death-rate between Leicester and Nottingham, the latter town, which has retained its pail closets, showing but a very slight decline in the prevalence of the disease. For some years past a limited number of patients suffering from pulmonary tuberculosis have been admitted into one of the blocks of the isolation hospital, and Dr. Millard gives an account of some of the after-histories. The patients are admitted in the first instance for a month only, and at the end of that time, if the case is making satisfactory progress, a second month's stay is granted subject to a payment of 10*s.* weekly. Calmette's ophthalmic tuberculin test has been applied during 1908 both at the hospital and the town-hall upon patients sent for the purpose by medical men, but Dr. Millard thinks that although the test is of undoubted value it is neither entirely reliable nor free from the serious drawback of, at times, setting up troublesome conjunctivitis. He advises the employment of a weak solution in the first instance. The Notification of Births Act, 1907, has not yet been adopted in this town owing to the unwillingness of the medical practitioners, and a voluntary system is at present in vogue which does not seem to have been attended with signal success. There is a crematorium in Leicester, but its popularity is not, after an existence of over six years, very great, only 14 cases having selected this method of material dissolution during 1908. Dr. Millard states that in the whole country (13 crematoriums) there were 795 cremations in 1908, while on the continent during the same period 4050 persons underwent cremation. The fees for cremation at Leicester is £2 2*s.* for residents and £5 5*s.* for non-residents.

Southend Borough.—Dr. O. G. Pugh succeeded Dr. J. T. O. Nash as medical officer of health of this district in June, 1908, and the latter has contributed a short report for the first half of the year. Dr. Pugh is, however, responsible for the whole of the vital statistics. One of the most satisfactory features in the history of the borough during 1908 was the continued low infantile mortality, which amounted to only 93·62 per 1000 births, a rate which is slightly below that of the previous year, when it was 94·05 per 1000 births. Dr. Pugh emphasises the necessity for the provision of sanatorium treatment of pulmonary tuberculosis, and he hopes that when the additions now being made to the isolation hospital have been completed it may be possible to utilise one of the wards for the educational treatment of patients suffering from this disease. As in many other of our large towns, a marked diminution of enteric fever has taken place in Southend during the last ten years, the death-rate for 1908 being 0·5 per 10,000 of the population. Of the indigenous cases 13 were ascribed to shell-fish, and it is to be noted that in four cases the onset of the disease took place only a week after the consumption of the shell-fish. In some of the 13 cases which were associated with the eating of shell-fish other members of the family partook of the shell-fish at the same time, but, except in one instance, only one member of the family contracted the disease. But in three instances the only member of the family to be attacked was the one who had eaten shell-fish. With reference to the utility of the isolation hospital the medical officer of health remarks that the hospital problem hardly arises in a place like Southend, where it is obviously desirable that cases occurring in hotels or lodging-houses should be at once removed to hospital owing to the financial consequences involved. As so many of the ratepayers of Southend obtain a livelihood by letting rooms it is improbable that there will be found in the borough any serious question as to the value of these essential institutions.

Sunderland County Borough.—Dr. Henry Renney embodies in his report for 1908 an interesting table showing the number of children born per 1000 women at child-bearing age, the rates ranging from 146 in 1899 to 130 in 1908. In the matter of small-pox the medical officer of health utters a warning note concerning the sinister operations of the Vaccination Act, 1907, in consequence of which measure there were in 1908 445 "conscientious" objectors, as against 60 in 1907. The case mortality of diphtheria has shown a steady diminution since the year 1890, but the prevalence of the disease, as measured by the notifications, has shown a marked increase during the last four years. For the last eight years the corporation has rented beds at the Stanhope sanatorium, and during that period 69 consumptive patients have undergone treatment therein. Of this total 40 are now dead, two are ill, and eight cannot be traced, while 19 are either "well" or "fairly well." Of the 21 patients who are still under observation two have been discharged nearly eight years and others from three to six years. Dr. Renney remarks that although sanatorium treatment arrests the disease it does not always prevent a recurrence, and hence the necessity for placing the patients under favourable conditions after discharge. This is unfortunately not very easy of accomplishment owing to the indisposition on the part of employers of labour to engage the once tuberculous, a fact which is becoming more and more apparent every day. These objections are due partly to an unreasonable dread of infection, partly to a belief that sanatorium treatment tends to induce slackness as regards work.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7786 births and 3711 deaths were registered during the week ending July 10th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 12·6 to 11·8 per 1000, was again so low as 11·8 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 14·0 per 1000, against 14·9 and 13·7 in the corresponding quarters of 1907 and 1908; the mean rate in London during last quarter did not exceed 13·5, against 14·0 and 12·7 in the two preceding corresponding quarters. The lowest recorded annual death-rates in the 76 towns last week were 4·5 in King's Norton, 4·9 in Hornsey, 5·2 in Willesden, and 5·6 in Tottenham, all being distinctly suburban districts; the rates in the other towns ranged upwards, however, to 16·8 in Middlesbrough and in Tynemouth, 16·9 in Wolverhampton, and 17·4 in Hanley. In London the recorded death-rate last week did not exceed 12·0, showing, however, an increase upon the exceptionally low rate in the previous week. The 3711 deaths in the 76 towns last week from all causes showed a further decline of 22 from the decreasing numbers in recent weeks, and included 341 which were referred to the principal epidemic diseases, against numbers declining from 393 to 321 in the four preceding weeks; of these 341 deaths, 138 resulted from measles, 64 from diarrhœa, 59 from whooping-cough, 39 from scarlet fever, 32 from diphtheria, and nine from "fever" (principally enteric), but not one from small-pox. The 341 deaths from these epidemic diseases last week were equal to an annual rate of 1·1 per 1000, against 1·0 in the previous week. No death from any of these epidemic diseases was registered last week in Stockport, Hornsey, Rochdale, Aston Manor, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·1 in Walsall, 3·3 in St. Helens, 4·6 in Coventry, and 5·0 in Wolverhampton. The fatal cases of measles in the 76 towns, which had declined in the four preceding weeks from 186 to 129, rose again last week to 138, and caused annual death-rates ranging upwards to 2·6 in Walsall, 3·0 in West Bromwich, 4·6 in Coventry, and 5·0 in Wolverhampton. The 64 deaths attributed to diarrhœa showed an increase of 15 upon the number in the previous week, and exceeded those returned in any preceding week of this year. The deaths from whooping-cough, which had been 57, 63, and 70 in the three previous weeks, declined again last week to 59, and caused the highest death-rates, 1·1 in Huddersfield, 1·2 in Derby, and 1·5 in Middlesbrough. The 39 fatal cases of scarlet fever showed a further slight increase upon the low numbers in the two preceding weeks, and included 15 in London and its suburban districts, four in Liverpool, eight in Manchester and Salford, and two in Newcastle-on-Tyne. Of the 32 deaths assigned to diphtheria, exceeding the number in the previous week by four, 13 occurred in London and its suburban districts, three in Manchester and Salford, and two each in Brighton, Southampton, and Birmingham. Only nine deaths were referred to "fever" in the 76 towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had steadily increased in the five preceding weeks from 2228 to 2537, had further risen to 2647 on Saturday last; 371 new cases of this disease were admitted to these hospitals during last week, against 468, 368, and 390 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 155 and 158 in the two previous weeks, declined again to 154 last week, but exceeded the corrected average number in the corresponding week of the five years 1904–08 by 28. The deaths in London directly referred to influenza declined last week to seven, from 13 and 11 in the two preceeding weeks. The causes of 28, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were again duly certified in London, Leeds, Bristol, West Ham, Bradford, Sheffield, Newcastle-on-Tyne, and in 52 other smaller towns; the 28 uncertified causes of death in the 76 towns included six in Liverpool, five in Birmingham, and two both in Sunderland and Reading.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 871 births and 462 deaths were registered during the week ending July 10th. The annual rate of mortality in these towns, which had been equal to 12·7 and 13·3 per 1000 in the two preceding weeks, declined again to 12·9 in the week under notice. During the 13 weeks of last quarter the death-rate in these Scotch towns averaged 16·0 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 14·0. The death-rates last week in these Scotch towns ranged from 11·5 in Greenock and 12·2 in Glasgow, to 14·1 in Aberdeen and 14·6 in Leith. The 462 deaths from all causes in the eight towns showed a decline of 15 from the number returned in the previous week, and included 36 which were referred to the principal epidemic diseases, against 56, 54, and 37 in the three preceding weeks. These 36 deaths were equal to an annual rate of 1·0 per 1000, corresponding with the rate in the previous week; the rate last week from the same epidemic diseases in the 76 large English towns was equal to 1·1 per 1000. Of the 36 deaths from these epidemic diseases in the Scotch towns, 12 resulted from whooping-cough, 12 from diarrhœa, seven from measles, two from both scarlet fever and diphtheria, and one from "fever," but not one from small-pox. The 12 fatal cases of whooping-cough showed a further slight decline from recent weekly numbers and included five in Glasgow and four in Edinburgh. The 12 deaths attributed to diarrhœa, exceeded those returned in the previous week by one; five occurred in Glasgow and four in Dundee. The fatal cases of measles, which had been 13, eight, and five in the three previous weeks, were seven last week, of which four occurred in Paisley and two in Glasgow. Both the deaths from scarlet fever were returned in Glasgow; and of the two from diphtheria, one each occurred in Glasgow and in Edinburgh. Only one death was referred to "fever" in the eight towns, and was certified as typhus in Dundee. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 64 and 71 in the two preceding weeks, declined to 61 in the week under notice, but exceeded the number in the corresponding week of last year by ten. The deaths in the eight towns last week included 25 which were referred to different forms of violence, of which 13 occurred in Glasgow, five in Aberdeen, and three in Edinburgh. The causes of 17, or 3·7 per cent., of the deaths in the eight towns last week were uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 15·7, 19·6, and 18·5 per 1000 in the three preceding weeks, declined again to 15·6 in the week ending July 10th, a lower rate than in any previous week of this year. During the 13 weeks of last quarter the death-rate in the city averaged 20·9 per 1000, whereas the mean rate during the same period did not exceed 13·5 in London and 15·8 in Edinburgh. The 119 deaths of Dublin residents from all causes registered last week showed a further decline of 32 from the numbers returned in the two preceding weeks, and included but three which were referred to the principal epidemic diseases, against eight and 13 in the two previous weeks. These three deaths were equal to an annual rate of but 0·4 per 1000, the death-rate from these same epidemic diseases being equal to 1·0 in London and 0·9 in Edinburgh. Of the three deaths from these epidemic diseases in Dublin last week, two resulted from diarrhœa and one from diphtheria, but not one from measles, scarlet fever, whooping-cough, "fever," or small-pox. The 119 deaths at all ages included 21 of infants under one year of age and 32 of persons aged upwards of 60 years; both these numbers showed a considerable decline from the numbers in the previous week. Three inquest cases and two deaths from violence were registered during the week; and 49, or 41·2 per cent., of the deaths occurred in public institutions. All the causes of death registered in the city last week were again duly certified either by a registered medical practitioner or by a coroner; in London, also, all the causes of death last week were duly certified, but in Edinburgh the proportion of uncertified causes of death was equal to 6·4 per cent.

VITAL STATISTICS OF LONDON DURING JUNE, 1909.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·5 per 1000 of the population, estimated at 4,833,938 persons in the middle of the year; in the three preceding months the rates were 5·9, 5·4, and 6·1 per 1000 respectively. The lowest rates last month were recorded in Kensington, Hampstead, Stoke Newington, Holborn, Finsbury, and Camberwell; and the highest rates in Paddington, Chelsea, the City of Westminster, St. Marylebone, Lewisham, and Woolwich. The prevalence of scarlet fever again showed an increase last month; among the various metropolitan boroughs this disease was proportionally most prevalent in Paddington, Chelsea, the City of Westminster, St. Marylebone, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 2539 scarlet fever patients at the end of last month, against 2412, 2143, and 2207 at the end of the

* Including membranous croup

three preceding months; the weekly admissions averaged 353, against 278, 262, and 318 in the three preceding months. Diphtheria was rather less prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Hammersmith, Fulham, Holborn, Shoreditch, Battersea, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1103, 1012, and 920 at the end of the three preceding months, had further fallen to 890 at the end of last month; the weekly admissions averaged 105, against 121, 109, and 108 in the three preceding months. The prevalence of enteric fever showed a slight increase last month; this disease was proportionally most prevalent in Paddington, Kensington, Chelsea, Hackney, Shoreditch, Bermondsey, Battersea, and Greenwich. There were 58 enteric fever patients in the Metropolitan Asylums Hospitals at the end of last month, against 87, 57, and 49 at the end of the three preceding months; the weekly admissions averaged nine, against seven, nine, and eight in the three preceding months. Erysipelas was proportionally most prevalent in the City of Westminster, St. Marylebone, Finsbury, Bethnal Green, Stepney, Southwark, and Deptford. The 33 cases of puerperal fever notified during the month included four belonging to Fulham, and three each to Hackney, Lambeth, Wandsworth, and Woolwich Of the 12 cases notified as cerebro-spinal meningitis, two belonged to Hackney, two to Lambeth, and two to Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the five weeks ending July 3rd the deaths of 5137 persons belonging to London were registered, equal to an annual rate of 11·1 per 1000; in the three preceding months the rates were 21·4, 15·0, and 12·9 per 1000. The lowest rates recorded last month were 5·6 in Stoke Newington, 7·7 in Greenwich, 8·0 in Lewisham, 8·3 in Hampstead, 9·0 in Hackney, and 9·5 in Wandsworth; the highest rates were 13·3 in Poplar, 13·5 in Bethnal Green, 15·0 in Bermondsey, 15·9 in Finsbury, and 22·9 in the City of London. The 5137 deaths from all causes included 495 which were referred to the principal infectious diseases; of these, 240 resulted from measles, 38 from scarlet fever, 34 from diphtheria, 109 from whooping-cough, ten from enteric fever, and 64 from diarrhœa, but not any from small-pox, from typhus fever, or from ill-defined pyrexia No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, St. Marylebone, Stoke Newington, Hackney, Deptford, Lewisham, and Woolwich; and the highest rates in Hammersmith, Fulham, Finsbury, Shoreditch, Poplar, and Greenwich. The 240 fatal cases of measles were slightly below the corrected average number for the corresponding period of the five preceding years; the greatest proportional mortality from this disease occurred in Paddington, Hammersmith, Fulham, Holborn, Finsbury, Shoreditch, and Poplar. The 38 deaths from scarlet fever were nine fewer than the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Hammersmith, the City of Westminster, Wandsworth, Camberwell, and Deptford. The 34 fatal cases of diphtheria showed a decline of 13 from the corrected average number; the highest death-rates from this disease were recorded in Hammersmith, St. Pancras, Shoreditch, Bermondsey, and Woolwich. The 109 deaths from whooping-cough were 32 below the corrected average number for the corresponding period of the five preceding years; the greatest proportional mortality from this disease occurred in Hampstead, Finsbury, Shoreditch, Poplar, and Bermondsey. The ten fatal cases of enteric fever were considerably below the average; the ten deaths belonged respectively to Paddington, Fulham, Hampstead, Islington, Hackney, Shoreditch, Poplar, Southwark, Lambeth, and Battersea. The 64 deaths from diarrhœa were 35 fewer than the corrected average number; this disease was proportionally most fatal in Hammersmith, Bethnal Green, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 16 per cent. below the average for the same period of the five preceding years.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 84 per 1000. The lowest rates of infant mortality were recorded in Chelsea, St. Marylebone, Stoke Newington, Lambeth, Wandsworth, and Greenwich; and the highest rates in Kensington, Fulham, the City of London, Bethnal Green, Poplar, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: H. W. Finlayson to the *Blake*; and H. E. Tomlinson to the *Assistance*. Staff-Surgeons: A. A. Forrester to the *Pyramus*, on recommissioning; A. F. Fraser to the *Terrible*, and to the *Flora*, on recommissioning; G. R. MacMahon to the *Terrible*, for medical charge on voyage to Colombo, and to the *Penguin*, additional, for Sydney Medical Depôt; W. L. Martin and S. H. Woods to the *Terrible*, and to the *Cambrian*, on recommissioning; R. Hughes to the *Terrible*, and to the *Psyche*, on recommissioning; P. F. Alderson to the *Vivid*, additional, for Pembroke Dockyard, temporarily; C. E. C. Stanford to the *Blenheim*; E. T. P. Eames to the *Terrible*, for voyage home; and D. V. Lowndes to the *Philomel*, on recommissioning. Surgeons: A. T. Rivers to the *Terrible*, and to the *Flora*, on recommissioning; J. Fullarton to the *Terrible*, and to the *Pioneer*, on recommissioning; F. R. Featherstone to the *Pembroke*, additional, for disposal; L. M. Morris to the Royal Marine Division, Plymouth; G. T. Verry to the *Lord Nelson*; G. O. M. Dickenson to Haslar Hospital; J. Bourdas to the *Terrible*, for voyage home; and W. E. Ormsby to the *Halcyon*, additional, for the *Skipjack*.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Notts and Derby Mounted Brigade Field Ambulance: Lieutenant Alexander R. Tweedie to be Captain (dated March 27th, 1909).

2nd Northumbrian Field Ambulance: Second Lieutenant Arthur Cecil Hays McCullagh, from the Unattached List, to be Lieutenant (dated April 1st, 1909).

1st Northern General Hospital: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel John Victor Walton Rutherford, from the 1st Northumbrian Brigade, Royal Field Artillery, to be Lieutenant-Colonel (dated March 30th, 1909).

Attached to Units other than Medical Units.—Lieutenant Samuel Martyn to be Captain (dated April 1st, 1908).

For Attachment to Units other than Medical Units.—Henry Michael Bayer (late Surgeon-Lieutenant, 5th (Irish) Volunteer Battalion, The King's (Liverpool Regiment)) to be Captain (dated May 1st, 1909). Douglas George Rice-Oxley to be Lieutenant (dated May 19th, 1909).

ROYAL ARMY MEDICAL COLLEGE EXAMINATION.

The following is the list of prize-winners at the recent examination at the termination of the junior course at the College:—Lieutenant H. S. Ranken, R.A.M.C., the Herbert, De Chaumont, Tulloch Memorial, Ranald Martin, and Marshall Webb prizes; Lieutenant J. A. Manifold, R.A.M.C., first Montefiore prize; Lieutenant C. L. Franklin, R.A.M.C., second Montefiore prize; Lieutenant A. M. S. Jukes, I.M.S., Parkes Memorial prize; and Lieutenant B. Gale, I.M.S., Fayrer Memorial prize.

3RD SOUTH MIDLAND FIELD AMBULANCE.

The medical profession of Bristol afforded some practical evidence of their sympathy with the 3rd South Midland Field Ambulance section of the Royal Army Medical Corps by subscribing for a drum major's staff, which was presented to the corps on July 9th by the officer commanding the South Midland Division, Brigadier-General H. A. Raitt, C.B. There was a large attendance, including Dr. R. Shingleton Smith, Mr. F. Richardson Cross, and Lieutenant-Colonel A. W. Prichard (commanding officer of the corps). Brigadier-General Raitt in an interesting speech said that the corps deserved special recognition on account of its being amongst the first in England to reach its establishment.

TERRITORIAL NURSING.

A meeting of the nursing committee of the Gloucester

Territorial Forces County Association was held on June 28th at the Royal Infirmary, Bristol. The Duchess of Beaufort, who presided, said that the committee had to provide a nursing staff for the 2nd Southern General Hospital, consisting of two matrons, 30 sisters, and 88 nurses. She explained that to volunteer for the service entailed no obligation unless and until the Territorial Forces were mobilised. Miss Baillie, the organising matron, said that she had received a good proportion of the necessary applications, and it was decided on her recommendation to enrol these.

THE ROYAL MILITARY (FAMILIES) HOSPITAL, SHORNCLIFFE.

On July 10th Princess Christian of Schleswig-Holstein opened the new Military (Families) Hospital at Shorncliffe. Major S. H. Fairrie, R.A.M.C., explained to Her Royal Highness that the hospital had been constructed to supersede the old wooden hospital which had been in use for the past seven years. The present building had been erected at a cost of about £10,000, and it would accommodate 35 in-patients.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on July 13th, Sir C. J. Thomas, K.C.B., being in the chair, the sum of £55 was distributed among the several applicants.

There will be an examination for the rank of staff-surgeon at Devonport on July 27th and 28th, from 10 A.M. until noon and from 2 to 4 P.M. each day.

Correspondence.

"Audi alteram partem."

THE RESTRICTION OF UNQUALIFIED PRACTICE AND THE SALE OF SECRET REMEDIES IN GERMANY.

To the Editor of THE LANCET.

SIR,—In spite of our enlightened times quackery is still rampant to an alarming extent. It is a psychological symptom that does not fit in with the boasted results of compulsory education and sixpenny editions of monistic theories, especially when we find that not only the "ignorant" but also many who by their training or position ought to know better, entrust the care of their health to persons whose methods savour more of the medicine-man of darkest Africa than of the exponent of those achievements that may well be termed the greatest and noblest fruits of man's ingenuity for the benefit of his fellow creatures. The action of the General Medical Council towards deleting this blot on our vaunted civilisation[1] should find the warm support of all who really profess to take an interest in their brethren's health.

As this question is likely to be prominently before the public, a *résumé* of the recent efforts made in Germany in this direction should prove of interest to those best placed to judge of the efficiency and likelihood of success of the measures to be taken. As stated in the report issued by the Unqualified Practice Prevention Committee of the General Medical Council, the position in Great Britain and Ireland is to a great extent similar to the conditions existing in Germany. The art of healing in Germany is free to all except pharmacists who may wish to pursue this calling, the only restriction being that potent drugs may only be dispensed upon a qualified practitioner's prescription. Recently, however, the numerous unfortunate results attending the effects of indiscriminate doctoring have led to legal proceedings, the law regarding such cases as coming within the scope of the paragraphs affecting "bodily injury caused by carelessness," and has meted out punishment accordingly. The Government of the Fatherland, ever mindful of safeguarding th [illegible] to accomplish this object [illegible] evils: secret remedies an [illegible] The imperial law for the regulation of the sale of secret remedies has been in force for some time. Briefly, it forbids the public advertisement of 153 preparations, or the inclusion of any testimonials or vaunting recommendations referring to the supposed curative properties of the preparation in question. Further, the pharmacist has to assure himself that no potent drugs are contained, which may be sold only on production of a qualified practitioner's prescription. A list of preparations has been elaborated, including a large number of the more known patent remedies, against which these regulations are specially directed. In Table B, which contains the names of 30 preparations which may only be dispensed upon a prescription, we find the following, amongst others: Tucker's asthma cure, Battle's bromidia, Blair's gout and rheumatic pills, Williams's pink pills, and Morison's pills. In the 123 articles in Table A which may be sold without a prescription, but to which the above restrictions apply, figure: Elliman's universal embrocation (excepting for horses), Mother Seigel's pills and syrup, Beecham's pills, and Ayer's sarsaparilla. The closing of the press as a medium for advertising was naturally a hard blow, and this is actively followed up by the publication of warnings against various other advertised preparations, which appear from time to time in local papers on behalf of the different municipal health boards. In spite of these measures it is officially stated that in the financial year of 1898-99 £1,500,000 were spent in Germany on secret remedies, while in the period from January to October, 1908, 31,200 kilogrammes were imported, paying £7800 in Custom dues, and 40,400 kilogrammes were exported out of Germany.

It is a regrettable fact to have to confess that these regulations have failed in their object—viz., of stamping out the "secret remedy nuisance," as it is termed in Germany, and this is very largely due to the attitude assumed by those for whose benefit they were elaborated. A love of the supernatural, impatience, and credulity are the great assets in favour of the vendor of the "cure all ills" preparation, and in many instances it would appear as if a special pride were taken in abetting him in eluding this law, which so many regard as being created for the pecuniary benefit of the physician. This negative result led to the elaboration of a proposed Imperial Bill to regulate unqualified practice, and to place the sale of secret remedies on a uniform basis throughout the empire. This project is at present under consideration at the hands of the governments of the various Federal States before discussion at no distant date before the Reichstag.

To absolutely forbid unqualified practice is held to be inopportune, but those persons who without possessing a legal qualification wish to practise the art of healing on man or beast as a business will be required to comply with the following conditions:—1. To inform the local police authorities in writing, at the latest on beginning to practise, of their dwelling place and business address; this applies equally to any change of address or alteration in the "working." (The word "Betrieb" places this "traffic" on a par with a factory or a railway line.) 2. "Tradespeople of the above kind" (*sic*) will, upon demand, be required to supply the police authorities with full information regarding their antecedents and personal circumstances, as far as affecting their trade, especially, however, regarding their education and previous occupation. They will also be required to keep business books, which must on demand be produced and laid before the police authorities. Paragraph 3 is the most interesting, as it strictly limits the scope of work open to the enterprising quacks ready to comply with the above regulations. They are forbidden to treat either man or beast without in person conducting an examination; this excludes treatment by letter. In dealing with human beings, the treatment of syphilis, gonorrhœa, or chancre by such person is prohibited; this also applies to treatment by means of mystic procedures, use of hypnotism, or of anæsthetics not having a purely local action. The police are empowered to stop the further treatment of persons suffering from contagious diseases on the schedule of one of the States; or of affections dangerous to the community at large. Permission to exercise unqualified practice may be refused, or [illegible] and further practice rendered illegal on [illegible] f facts can be adduced prov[illegible]rade is likely to be injurious to the health of man or animal treated, or liable to endanger life; (2) if the clients are exploited in a swindling manner; or (3) if the unqualified practitioner has been legally [illegible] for contravening this law.

[illegible] projected Bill deals with the sup- [illegible] and allied evils. Should it pass, the Federal Council (Bundesrat) will be empowered to forbid the sale *and importation* of any contrivances or articles intended to prevent, alleviate, or heal illnesses, sufferings, or bodily injuries in man or beast, if their use is likely to prove detrimental to health, or if they are marketed in a manner intended to deceive or exploit the purchaser. A special commission is to be appointed to deal with such questions. More than half of the actual wording of the Bill is devoted to an enumeration of the punishment provided to deal with offenders against its provisions. False representations respecting the value or effects of such preparations in public advertisements will make the advertisers liable to a penalty of imprisonment for a period not exceeding one year, in certain circumstances coupled with a fine up to £150, or either of these punishments may be inflicted alone. Imprisonment up to six months and a fine not exceeding £75, or either form of punishment alone, will be incurred by whosoever publicly offers to treat persons or animals by mail; publicly advertises or recommends remedies, articles, or methods intended to prevent, alleviate, or cure venereal diseases, remove sexual impotence, increase sexual appetite, prevent conception, or procure abortion. The same penalties will be provided for whoever publicly advertises or recommends remedies, &c., intended to alleviate, prevent, or heal illnesses, suffering, or bodily injuries in man or beast without clearly indicating the composition and proportion of the ingredients of the preparation or the material point in the method advertised.

---

[1] THE LANCET, Jan. 23rd, 1909, p. 250

Unqualified persons, not registered according to this Act, who undertake upon payment to treat man or beast are liable to a fine not exceeding £7 10*s*. or imprisonment. Should such treatment be undertaken in a case where delay would prove dangerous no punishment will be inflicted, provided that the treatment lasts only until the aid of a qualified practitioner is obtained and is not of a nature forbidden to unqualified but "registered" persons. These are the principal offences, but punishments are included to be inflicted for minor transgressions against the provisions of the Bill. One paragraph (12) of the proposed law is interesting, as it further aims at shattering the foundation upon which the business of the manufacturer of secret remedies rests—publicity. When the press was closed to a section of these manufacturers by the law for the regulation of the sale of secret remedies to which reference has been made already, advertisements were sent through the post or distributed from house to house. But paragraph (12) of the Bill states that public advertisement in the sense of this law will also apply to the distribution of recommendations, letters of thanks, testimonials, and similar communications to a large circle of persons.

German medical opinion, although in favour of the proposed regulations, does not consider them to be stringent enough in view of the vital importance of the issue at stake. Yet they represent the utmost that the Government hopes to achieve when the Bill will be under discussion. As the elaboration of a highly civilised state they command the greatest attention and indicate the lines upon which one country is actively engaged in repressing unqualified practice and its kindred evils. One important postulate is the active coöperation of the public; will it be forthcoming in England as well as in Germany?—I am, Sir, yours faithfully,

Darmstadt. G. P. FORRESTER.

RELATION OF ACIDOSIS TO THE CARBON DIOXIDE OF THE BLOOD IN DIABETIC COMA.

To the Editor of THE LANCET.

SIR,—In your issue of June 19th you inserted a communication by Dr. A. P. Beddard, Dr. M. S. Pembrey, and Dr. E. I. Spriggs with the above heading. I ask you to be good enough to insert this letter in reply to the line of argument they have set forth.

The problem dealt with is the source of the occurrence of death in association with diabetic coma. To go back to the beginning, the matter was referred to in an article by me entitled, "On the Acetone Series of Products in Connexion with Diabetic Coma," that was published in THE LANCET of July 12th, 1902. In this article I gave an explanation touching the causation of death which was afterwards taken exception to by the above-named authorities. In my lectures on the Pathology and Treatment of Diabetes recently delivered at the Royal College of Physicians of London, and published in THE LANCET,[1] I criticised the line of argument they had put forth, and the present discussion emanates from what I felt it necessary to state. They adduce some experimental work in support of their contention, and draw from it deductions which, owing to their omission of a factor of consideration in connexion with the matter, I do not concede they are justified in doing.

The point at issue is the position in which carbon dioxide stands in relation to the fatal termination that occurs. We know that the production of carbon dioxide is intrinsically mixed up with living action, and that its removal from its seat of generation in the tissues is essential to the continuance of life. All admit that it is through the instrumentality of respiratory action that its removal is effected. The mechanism of removal works in an automatic manner. A special adaptability is given to the blood circulating through the tissues for taking on the generated carbon dioxide through the medium of the alkaline ingredients with which it is provided. Further, the muscular action concerned in pumping off from the lungs the carbon dioxide that has reached the blood and is designed to be discharged from the body is placed under nerve control, which affords a means of adapting the work to be performed to the variable requirements existing under the different circumstances that may chance to present themselves. These are the fundamental facts met with, and a failure anywhere in the performance of what is wanted suffices to lead to an arrest of living action.

In my lectures I say, "The continuance of life is dependent upon the elimination of the carbon dioxide produced as a result of vital activity. The sodic carbonate and, to a certain extent, the sodic phosphate, are the cardinal agents for conveying the carbon dioxide from the tissues to the lungs. If through any abnormality there should be an entry of acid into the blood, establishing what is known as a state of acidosis, the alkaline base will be appropriated by it, and thence be prevented contributing to the transport function as normally designed it should do." In unison with this view interference with the working of the respiratory mechanism in operation is regarded as affording sufficient to account for the fatal issue in connexion with diabetic coma without bringing into the question any assumed outside or extraneous cause.

My opponents have put forward some experimental results that they have obtained as controverting the view to which reference has been made. Let us see in what position they stand under the light of critical examination.

Their experiments, in effect, concur in showing that diabetic coma blood is not to be taken as exempt from absorbing power over carbon dioxide. They contend that if the wrong procedure in acidosis were due to non-removal of carbon dioxide from the tissues the blood logically should not be able to take it up. "So long as the body is alive," they say, "it will continue to produce carbon dioxide. Whenever the blood is unable to remove it as fast as it is produced, carbon dioxide must accumulate in the tissues, and if it accumulates then its tension in the tissues must be raised." The raised tension spoken of they consider ought to render itself evident, which they state is not found to be the case. Again, "if the 'alkalinity' of the blood begins to fall, and if carbon dioxide begins to accumulate at an increased tension in the tissues, the blood in the capillaries must be exposed to an increased tension of carbon dioxide. And although the reduced 'alkalinity' of the blood might prevent its taking up a normal quantity of carbon dioxide, nevertheless such gas as the blood did take up would be under an increased tension." As a matter of fact, they assert, the tension, instead of being increased, is much below the normal value.

Their argument is based entirely on the effects of gaseous tension. They completely ignore any other point of consideration in connexion with the matter. Nothing is anywhere to be found in their communication about any other factor being concerned in the question. I ask if this is permissible, seeing that both in the case of oxygen and carbon dioxide, combination—in the one case with hæmoglobin and in the other with alkaline basic material—constitutes an all-important item of consideration in connexion with the gaseous transport service performed by the blood.

---

[1] Vide THE LANCET of Dec. 12th, 1908, p. 1727.

Obviously, when oxygen and carbon dioxide are respectively in their states of combination (whatever may be the precise degree of potency of combination that exists) they cannot exert the tension influence they are capable of doing when present in a free state Throughout, carbon dioxide is dealt with as though it were existing in a free state It is logical to infer that blood may be capable of taking up carbon dioxide when presented to it in a free state, whilst it may be incapable of doing so when it has to be dissociated from a pre existing state of combination Is it to be conceived that carbon dioxide as it is produced is thrown in a free state into the tissues? We know that it is produced, but we do not know the precise form of existence in which it first presents itself For my own part, however, I consider that it ought to be regarded as existing in some form or other of combination, and that a dissociation operation has to be performed before it reaches the blood

It is admitted that in advancing acidosis there is a concurrent descent in carbon dioxide elimination This falls in intelligibly with the view that, through the abnormal acid development, the alkaline basic material of the blood, becoming saturated with fixed acid, loses its transport power in connexion with carbon dioxide The *manner in which* the condition, even after it has advanced to the stage of coma, becomes rectified by the introduction of sodic carbonate into the blood equally tells in the same direction

My opponents, in commenting upon my view, fail to put it in a correct form They say, "This view is based upon the assumption that the decrease of carbon dioxide in the blood is primarily due to the inability of the blood to *combine* [the italics are mine] with more carbon dioxide than it is found to contain" The idea here conveyed does not strictly represent my contention. I hold that the blood with its lessened transport capacity an in its sodic carbonate content, source of its transport power, r dissociating and taking up carbon dioxide from the tissues, whilst still to a certain extent capable of taking it up when presented to it in a free form I consider the circumstances existing justify this conclusion, and that to escape from error the matter requires to be looked at not only from one but from all points of view.

The hyperpnœa that is associated with diabetic coma fits in with the view that I contend for in connexion with the matter under consideration I contend that it is owing to the respiratory mechanism being rendered ineffective that the result met with is attributable The object of respiration is to provide for an adequate supply of oxygen to the tissues and an adequate removal of carbon dioxide from them Let either of these operations be defectively carried out, and it will be found that the defectiveness shows itself by forced respiratory muscular activity being called into play in a manner representative of an effort of nature by compensatory action to set things right In the ordinary course of events when carbon dioxide is not being removed from the tissues to a proper extent increased respiratory movement is automatically induced by the effect of the condition existing (I put it in this broad way) upon the respiratory nerve centre This is exactly what is noticed in association with the state of breathing belonging to diabetic coma, and I consider that defective removal of carbon dioxide from the tissues is the rational factor to look to as standing at the foundation of what is observed We know that acidosis by its effect upon the sodic carbonate of the blood impairs the transport power of the blood for carbon dioxide We know also that the actual transport of carbon dioxide becomes correspondingly lessened as the acidosis advances, and if this lessening goes on it must necessarily follow that a point cannot escape being reached which is incompatible with the continuance of life There exists manifest evidence of default of respiratory efficiency, and death is to be satisfactorily accounted for without going outside the faulty respiratory capacity

Hyperpnœa is of itself indicative of the involvement of respiratory action in the issue It reveals the fact that the respiratory mechanism is not automatically meeting the existing respiratory requirement Douglas and Haldane, in an article on the Regulation of Normal Breathing published last month in the *Journal of Physiology* (Vol XXXVIII, No 5), have brought the question under consideration in connexion with the effect of forced muscular exertion They refer to the formation of lactic acid in the muscles as a result of excessive muscular work and to its leading to the production of hyperpnœa by its stimulating effect upon the respiratory centre A close parallelism is to be traced, from what they say about fall of carbon dioxide alveolar pressure, between the state thus induced by a call upon respiratory action that cannot at the moment be adequately met and the state associated with diabetic acidosis The respiratory capacity is in default from the excessive call in a direct manner made upon it in the one case, and may it not be rationally concluded that a similar state of default stands at the foundation in the other It is clearly made evident that *a low carbon dioxide alveolar pressure is not to be taken as* meaning absence of want of more effective removal of carbon dioxide from the tissues

Contending as I do that the view which refers the phenomena in diabetic coma to defective removal of carbon dioxide stands good, there is no need for seeking any other Dr Beddard, Dr Pembrey, and Dr Spriggs have reproduced in their article the view propounded by themselves and the comment made by me upon it in my College of Physicians' lectures As I have nothing further to say upon this matter, I leave it in the position in which it stands

I am, Sir, yours faithfully,
F W PAVY

WHO SHALL INSPECT THE SCHOOL CHILDREN?

To the Editor of THE LANCET.

SIR,—May I supplement your remarks in a recent leading article as to the respective merits of inspecting school children in county areas by (1) medical officers of health, (2) other local practitioners, and (3) recently qualified inspectors *ad hoc* Last first

This third system, you say, "makes for unity of method" I beg to deny it It gives temporary unity over width of area But the inspectors, with very few exceptions, soon tire of inspecting 50 children a day and writing up the records, £250 a year does not satisfy them for long, and they go The children they have seen are inspected by a different man on each triennial occasion By the time the new man has assimilated his method to that of his predecessor he also goes Nay, even the coordinator, the county medical officer, may go The unity is lost "It prevents, or should prevent, friction" On the contrary, it causes it Even if the young inspector have tact, he takes long to know local conditions, he may never meet the local medical officer of health, and misunderstandings are easy Several of his duties are also those of the medical officer of health, he will exclude contagious or infectious cases at his visit, but he must leave consequent action in their houses and school mainly to the medical officer of health and sanitary inspector Is this likely to secure efficiency or prevent friction? "Dual control must obtain in certain particulars—and the arrangement is not without some advantages" There can be no advantages in duality of control

The second system of employing local practitioners has the considerable advantage of making for unity in any one area over a length of time—longitudinal as opposed to lateral, chronologic to geographic, unity But if you suggest a different practitioner for each school, how am I to secure lateral unity over the 250 schools in Herts? If, instead, you suggest grouping of schools, the advantage of employing local practitioners is gone They will be inspecting each other's patients more than their own, they will not be in touch with the home conditions and parents of most of the children they inspect Medical practices are not *coterminous* with school areas And think of the friction then

The first system of employing medical officers of health seems to me for the counties the only one feasible in the long run, supplemented, if needs be for the present, by the help of one or two local practitioners in the larger areas Here is a compact body of chosen men, whose authority must already be recognised by their brother practitioners in regard to notification and sanitation Sufficient lateral unity is secured without difficulty, longitudinal unity is secured, for each child and each district, even should the county medical officer be changed Longitudinal unity is essential for the sake of the individual child, lateral for the sake only of statistics But the latter is of very slight—if, indeed, of any scientific—value in the comparison

Treatment is a different thing. The inspector gives the defective child a note to its parents to advise medical or domestic attention to a certain organ or condition of the body. Under the Children Act, 1908, Section 12, the parent is compelled to secure medical aid if required. But he gets it where he will, and no well devised system will give opportunity for influencing parents to leave their usual medical attendants. Above all, the employment of medical officers of health, the only body of men accustomed to consider prevention of disease in the mass, brings nearer the day, to which all authorities in public health appear to be looking forward, in which the medical inspection of school children will be a most essential part of the combined duties of medical officers of health uniformly, except in the large towns, throughout the country. Which system will best pave the way? I am, Sir, yours faithfully,

July 7th, 1909. F. E. Fremantle.

⁂ We feel that the very short experience of the inspection of school children which this country has had does not warrant anyone in speaking with Dr. Fremantle's emphasis. His statement (in which he denies the accuracy of our arguments) that medical inspectors will tire of their work, and that consequently the children will be continually inspected by new persons, is a prophecy the truth of which has yet to be gauged, especially as his words seem to carry with them the inference that the part-time medical officers of health, whose salaries are often quite small, will never tire of their work. We think that Dr. Fremantle overstates the claims of medical officers of health as experts in the "prevention of disease in the mass," and is generalising a little fearlessly from the position in Hertfordshire, which county is after all laterally, longitudinally, and geographically of limited area.—Ed. L.

INSTRUCTION IN ANÆSTHETICS FOR DENTAL STUDENTS.

To the Editor of The Lancet.

Sir,—The President of the College of Surgeons of England sees no objection to the publication of the accompanying correspondence; I should feel obliged therefore if you could find room for it in your next issue.

From the reply of the College I think it is apparent that, as far as general anæsthetics are concerned, the recent regulation is intended to apply only to the administration of nitrous oxide. I am, Sir, yours faithfully,

J. Fredk. W. Silk.

Devonshire-street, Portland-place, W.

[Copy.]

July 7th, 1909.

To the President of the Royal College of Surgeons of England.

Dear Sir,—Our attention has been drawn to a regulation lately issued by the Council of the Royal College of Surgeons, by which, after October 1st next, candidates for the diploma "L.D.S." will be required to receive "a course of practical instruction in the administration of such anæsthetics as are in common use in dental surgery."

As teachers of anæsthetics at some of the principal medical schools in London we take the liberty of pointing out to you that this particular phrasing (in common use, &c.) has already been understood in some quarters to include such substances as ethyl chloride, ether, chloroform, and the chief local anæsthetics.

We can hardly believe that this interpretation was in the mind of the Council when the regulation was originally framed, for it is obvious that, if so interpreted, many dental students would, on the strength of such instruction, claim the right to administer chloroform and other drugs; a possibility which in our opinion would be highly objectionable [illegible] the Council will see its way to issuing a [illegible] the instruction is to be confined to the [illegible]

[illegible] remain, yours obedient[illegible]

J. Blumfeld, [illegible] Hospitals.
C. C. Braine, [illegible]
T. G. A. Burns, Middlesex.
R. Gi[illegible], St. [illegible]
R. J. [illegible]
G. Rowell, Guy's.
J. F. W. Silk, King's College.

[Reply.]

Royal College of Surgeons, Lincoln's Inn-fields, W.C.,
July 9th, 1909.

Gentlemen,—I am desired by the President to inform you that he submitted your letter of the 7th inst. to the Council at their meeting yesterday, and that in reference thereto the Council adopted the following resolution, viz.: That the signatories to the letter be informed that the regulation to which they refer was adopted by the Council after full consideration of the different views which have been expressed regarding the administration of anæsthetics, and that the Council are not prepared to admit that the general anæsthetics specified by the signatories are "in common use in Dental Surgery," and must adhere to their decision.

I am, Gentlemen, your obedient Servant,
S. Forrest Cowell, Secretary.

TUBERCULOSIS DURING THE FIRST YEAR OF LIFE.

To the Editor of The Lancet.

Sir,—It is hardly yet sufficiently realised that tuberculosis is a common affection during the first year of life and not infrequent in the first six months. The following statistics, kindly collected for me by Miss A. Sanderson, of a series of infants of this age recently under my care in the Belgrave Hospital for Children, show this very clearly. Total number admitted, 501; total number of deaths, 219; post-mortem examinations, 127; number found tuberculous, 17. Of these infants there were in the first three months of life, 2; second three months, 3; third three months, 6; fourth three months, 6. The youngest child was a girl of seven weeks with tuberculous bronchial glands. Holt found tuberculosis in 26 under six months (5 under three months), 31 in the second half year of life, and 32 between two and five years. Still gives figures, based on 500 consecutive cases, as 22 and 60 for the two half years, and 130 in the second year of life, as against Holt's 39 in the second year. If cases of tuberculous meningitis are taken we find such statistics as: 14 out of 67 under one year (Holt), 3 out of 63 (Oxley), 18 out of 130 (Still). Of 54 cases under five years, which I collected two years ago, 10 were under one year, and of these 3 were under six months. Of the 17 cases, 9 were miliary tuberculosis, 2 miliary tuberculosis and meningitis, 2 meningitis, 1 pulmonary tuberculosis and meningitis, 1 pulmonary tuberculosis, 1 tuberculous broncho-pneumonia, and 1 tuberculous bronchial glands.

The difficulty of obtaining accurate details of the previous diet renders any conclusions as to the mode of infection open to error. A boy, nine months old, who died from miliary tuberculosis, was said to have been breast-fed until five days before admission. A girl of 12 weeks had had cows' milk for a week, and her mother was probably tuberculous. A boy of nine months had been fed on various articles of food but no cows' milk; his father recently had died from "bronchitis." Two girls of five and six months had been partly bottle-fed; their fathers probably were phthisical. Another girl of nine months had a phthisical sister. A breast-fed girl of eight months, who died from tuberculous broncho-pneumonia, lost her father a week previously from phthisis. A boy of ten months, who had tuberculosis of the right lower lobe, was said to have been entirely breast-fed for nine and a half months. A child of four months was breast-fed for three months and then on the breast with Nestlé's milk and milk-and-water in addition; his mother suffered from "chest." In the other eight cases the possibility of infection through cows' milk was greater.

These few cases indicate the frequency of tuberculosis in the first year of life and the probability that many of them are due to direct infection from a phthisical relative. What is wanted is a careful record of cases in the better classes of life, showing exactly what the possibilities of infection from another or by milk may be. Provided that an infant is brought in contact with a phthisical nurse or relative, it is infinitely more probable that subsequent tuberculosis is due to direct infection rather than to the milk-supply.

I am, Sir, yours faithfully,
Edmund Cautley, M.D. Cantab.,
Physician to the Belgrave Hospital for Children and to the Metropolitan Hospital.

Upper Brook-street, July 8th, 1909.

SYMMETRICAL LIPOMATA OF THE BROAD LIGAMENTS.

To the Editor of The Lancet.

Sir,—In the course of the pathological examination of the appendages in a case of ovarian fibroma and multiple fibroids of the uterus, removed from a woman, aged 51 years, by Professor H. Briggs, to whom I am indebted for the material, the condition of symmetrical lipomata of the broad ligaments was found. The tumour on the right side was a flattened ovoid, of the size of a broad bean, lying between the layers of the broad ligament at the posterior aspect of the fimbriated end of the right Fallopian tube. It was soft in consistency, and on section presented the characters of a fatty tumour. The tumour on the left side was somewhat less flattened, and contained two minute thin-walled clear cysts; *in size and position it corresponded* closely with the tumour on the opposite side, and, except for the small cysts, was of a uniformly fatty nature. Microscopically the lipomatous nature of the tumours was fully established, together with the demonstration, in the tumour of the left side, of a columnar epithelial lining to the small cysts, suggesting an origin from Kobelt's tubules. Lipomata of the broad ligaments are so rare as to excite interest; the occurrence, however, of symmetrical lipomata in this situation is perhaps sufficiently uncommon to warrant publication. The tumours from their position and size must have been symptomless, but whether, as suggested by Hektoën, a trophic influence played a part in their etiology, it is not easy to determine.

I am, Sir, yours faithfully,

E. EMRYS-ROBERTS, M.D. Liverp.,
Demonstrator of Pathology, University of Bristol;
late Subcurator of the Pathological Museum,
University of Liverpool.

July 9th, 1909.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—I am much annoyed to find that certain daily newspapers have published portions of an article of mine which appeared in the *Practitioner* of this month. My permission was not asked for this proceeding, and, if it had been, would certainly have been refused.

This unwarrantable liberty is a sad example which too clearly illustrates the decay in good manners of the British daily press, which has now reached the low level of the American daily press. I think that, with some obvious exceptions, for the public press to discuss medical questions in their columns is a serious impropriety.

I am, Sir, yours faithfully,

July 9th, 1909. DYCE DUCKWORTH.

THE ROUTINE USE, BY THE OPEN METHOD, OF A MIXTURE OF CHLOROFORM AND ETHER.

To the Editor of THE LANCET.

SIR,—Dr. Alexander Brown in THE LANCET of July 10th discusses the paper of the above title communicated by Dr. F. W. Hewitt and Dr. J. Blumfeld. He points to an apparent discrepancy between the authors' dictum in regard to the method of administration and the earlier writings of one of them (Dr. Hewitt), and he asks for guidance. As one who has in the past taken much interest in the study of inhalation methods, I may perhaps be able to throw some light upon the subject.

It is, I think, imperfectly appreciated how vastly different results may be obtained in accordance with simple variations in the technique of administration of anæsthetics on an open mask. I know from personal experience how one is liable to criticise the qualities of a particular sample of anæsthetic whilst overlooking the important bearing of the qualities of the method by which it is given. If a frame of the Skinner or Schimmelbusch type, covered with lint or closely woven flannel, be held so that it does not touch the patient's face, then it is not unusual to find that such mixtures as the A.C.E. or C.E. will not be efficient in inducing anæsthesia. If, however, the framework be adapted to fit closely but lightly upon the face, and the covering be formed of a loosely woven fabric, such as domette or a thin flannel, then an entirely different set of conditions regarding evaporation is set up. The respirations in this case pass wholly, or almost wholly, *through* the meshes of the fabric and not merely *over* its surface, and in this way a perfectly efficient concentration of vapour may be inhaled. It is indeed thus that the open ether method is rendered practicable, and it is from neglect of this simple principle that it fails.

This adaptation of frame and cover has a further highly important bearing upon the continued administration of vapours, for it presents the most favourable conditions under which the vapour strength may be regulated. By varying the proportional part of the total area of fabric (e.g., one-quarter, one-half, &c.) which is moistened with the anæsthetic, the percentage of vapour inspired is made to vary in accordance. The relation is certainly not in direct proportion, but it is sufficiently close to afford a greater control than may be effected by any way of using other forms of masks, either open, such as the ordinary Skinner's, or semi-open, such as the Rendle cone. There is also a decided objection to the inflated rubber pad which is fitted to the semi-open inhalers. In the absence of special precautions this is liable to induce a degree of obstruction to free respiration, and the substitution of a lightly resting metal frame results in a far happier type of breathing.

The open method of administering anæsthetics is capable of still more precise adjustment, and I think that the plan which I devised of using the A.C.E. mixture upon an open cover divided into four actual quadrants may be found to prove more efficient in less expert hands, but for a further account of these matters I may refer Dr. Brown to my papers in the *British Medical Journal* of August 4th, 1906, and Oct. 6th, 1907, p. 874.

Of the relative merits of the C_2E_3 mixture I have never had any personal experience, but I may perhaps be allowed to express the hope that Dr. Hewitt and Dr. Blumfeld will have success in their advocacy of a method which, of its kind, I am convinced will tend to afford the widest efficiency.

I am, Sir, yours faithfully,

London, W., July 13th, 1909. A. GOODMAN LEVY.

DELAYED CHLOROFORM POISONING.

To the Editor of THE LANCET.

SIR,—I was very interested to see the account by Dr. T. O. Somerville of the cases of delayed chloroform poisoning in THE LANCET of July 10th as I have had a somewhat similar experience, although fortunately my cases did not terminate fatally. Case 1 was a patient to whom chloroform was administered for a difficult delivery. The patient was under the anæsthetic from about three-quarters to one hour and nothing abnormal was noted during the administration, but as she was recovering consciousness she vomited up a coffee-coloured material; this continued to be vomited for about four or five hours and then ceased and she made a good recovery. Case 2 was a child to whom A C E. was administered for the removal of enlarged tonsils and adenoids. This was the worst case and vomiting continued for three days and was very severe. The vomit in this case was coffee-coloured and great prostration and exhaustion followed She recovered after careful treatment. Case 3 presented features practically identical with Case 1, but A C.E. was the anæsthetic administered, and the vomiting *did not occur till four hours after the return to consciousness.* I have satisfied myself that these cases were due to the use of a cheaper chloroform, acetone chloroform, for they occurred during a period when I was using this chloroform, thinking it reliable and feeling satisfied that it was cheaper; but I discontinued it and again used the purest chloroform, and no further cases of the kind happened.

These cases occurred in general practice and I have not full notes of them, but the cases reported *seemed to resemble* my own; and I thought it might be of interest to make a report of them.—I am, Sir, yours faithfully,

W. H. PAYNE, M R.C.S. Eng., L.R.C.P. Lond.

Vesta-road, Brockley, S.E, July 11th, 1909.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—We beg to appeal to the readers of this journal for help in the sad case of the late Mr. O E. Harris, Ph D. He was for over four years the demonstrator of chemistry to the Royal Institute of Public Health, during which time he rendered faithful and valuable services both to the institute and to sanitary science by his teaching and research work. Although delicate and greatly handicapped through a serious spinal deformity, the result of an accident in early childhood, he continued cheerfully and bravely in his work. Even during his last illness he was at work until a few days before his death, which occurred on May 31st last.

He has left a widow and six children between 12 and four years old totally unprovided for. Whilst endeavouring with the kind help of friends to obtain the admission of the children into suitable institutions, we are collecting a fund to provide for the urgent necessities of the family during the next few years. Any contributions sent to either of us will be gratefully received and acknowledged in this journal by

Yours faithfully,
CARL PRAUSNITZ, M.D. Breslau,
(Assistant Bacteriologist to the Metropolitan Asylums Board,
late Demonst [illegible] Royal Insti-
tute of P[illegible] " Grove-

N. H. TURNER, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H.
(Demonstrator of Public Health to the Royal Institute of Public Health), 35, Highbury-grove, London, N.
July 10th, 1909.

A SYSTEM OF DIET AND DIETETICS.

To the Editor of THE LANCET.

SIR,—May I say at once I am quite in agreement with Dr. Cautley that a brief article on a system of diet cannot be expected to include all the minutiæ of its subject. At the same time I would assert that however brief the description may be it is indisputably necessary, if the diet is to be prescribed intelligently, that it shall include and correctly describe prominent essentials, such as those which I criticised in my last letter. I refer to quantity and number of meals.

With regard to quantity, I mentioned that a minimum of nearly 11 ounces of meat a meal was unduly large for the majority of cases, and it will be noted that Dr. Cautley, although with evident reluctance, now inclines to my opinion, since he says, "It is possible to give the food in *four* meals of eight ounces each, *or to start with smaller quantities* and gradually increase them up to the full amount" (the italics are mine). I may here reciprocate Dr. Cautley's compliment to my mathematical ability by admiring the way in which he has added on another meal per day and so accommodated meals to quantity. Unfortunately, however, in adding on another meal, he has forgotten that Salisbury repeatedly emphasised "*five hours must elapse between meals,*" so that the hapless patient under Dr. Cautley's *régime* would have to partake of this fourth meal somewhere about midnight.

Turning to my second criticism, Dr. Cautley makes no attempt to justify his fairly weighty error of omission in not referring to the number of meals, nor, as already noted, to the interval which should elapse between meals, although a correct appreciation of both is indispensable to success. Surely Dr. Cautley cannot expect even the ablest practitioner to correctly guess these factors, yet, if he does not, I fail to understand how he can justify his assertion, "It does not need a high order of intelligence to understand the principles of the diet as laid down." I may, however, be doing Dr. Cautley an injustice; perhaps he includes these essentials with "the minutiæ of treatment which are not required."

With regard to exponents, I am glad to say I cannot refer Dr. Cautley to any, if by exponents he means men who exclusively practise the treatment. If, however, he refers to physicians who limit its application to carefully selected cases—the only way in which this or any other system of diet should be used—I can refer him to two whom I know do not use the quantities he mentions. In the meantime, may I support my remarks by referring Dr. Cautley to that admirable and accurate article on the subject in Dr. Burney Yeo's "*Food in Health and Disease,*" from which I quote the following extracts:—

(1) *Begin with 1 to 2 ounces* at each meal, and increase gradually to 3 to 4 ounces, and then to 5 to 6 ounces, and then to 8 ounces or more if it is well and easily digested.

(2) Five hours between each meal.

I am, Sir, yours faithfully,
Wimpole street, W., July 10th, 1909. ERNEST YOUNG.

JUNE SUNSHINE IN GUERNSEY.

To the Editor of THE LANCET.

SIR,—The accounts of the weather in England during June have been such dismal reading that it may be interesting to state that during the month 232 hours of sunshine have been recorded in Guernsey. From the beginning of the year until the end of June the total of sunshine was 1032 hours.

I am, Sir, yours faithfully,
HY. DRAPER BISHOP.
Health Office, Guernsey, July 6th, 1909

MANCHESTER ROYAL INFIRMARY.

(FROM OUR MANCHESTER CORRESPONDENT.)

THE STORY OF THE MANCHESTER ROYAL INFIRMARY.

THE Manchester Royal Infirmary, founded in 1752, has grown from small beginnings to the magnificent hospital which the King and Queen have so recently honoured. The old infirmary, during its sojourn in Piccadilly of over 150 years, underwent many transformations, which may be traced in various old prints, and which always took the form of enlargements of the previous building, until the grave and somewhat sombre edifice still dominating Piccadilly was found to cover as much of the open space as was desirable on hygienic grounds. The pressure on its accommodation for patients has for years been growing more and more severe, and the necessity for enlargement more urgent, so that various schemes, some for rebuilding on the old site, others for moving to a new one, have been considered and rejected in the course of a controversy which has been proceeding for 30 years or more. The subscribers at last instructed the board of management to obtain plans for rebuilding, but when these were submitted they declined to pass them. Lastly, in 1902, a new board was elected with instructions to provide a new hospital on a new site. A member of the old board, Mr. John Thompson, was elected chairman of the new one, and took the chief part in the sale of the old site to the corporation, but his death in 1904 terminated his invaluable services to the infirmary. He was succeeded by the present able chairman, Mr. (now Sir) William Cobbett, who has had the help of Mr. Charles Hopkinson as chairman of the building committee. As was to be expected, various sites were suggested, but that chosen in Oxford-road was presented by the trustees of the late Sir Joseph Whitworth to the University of Manchester for hospital purposes. The University has made additions to this site by purchase, increasing its extent to nearly 13 acres.

The medical and surgical requirements of the new hospital were laid down by the medical board after careful consideration, while the administrative requirements were specified by the late general superintendent, Mr. W. L. Saunder, the whole being further considered in detail by the board and embodied in the instructions to competing architects. Mr. J. J. Burnet, F.R.I.B.A., was architectural assessor, and he recommended the plans of Mr. Edwin T. Hall, V.P., R.I.B.A., and Mr. John Brooke, F.R.I.B.A. They were, with some modification of detail, adopted, and the splendid new infirmary is the result. The accommodation is ample for 592 patients and 339 resident officers, nurses, and servants. The equipment and furnishing have been a heavy task, carried out mainly by Mr. Saunder's successor, Mr. Walter G. Carnt, whose ability and knowledge have been greatly appreciated by the furnishing committee. The cost of the buildings and equipment, purchase of part of the site, redemption of chief rents, and interest on bank overdraft, &c., has been approximately £500,000. In addition, about £25,000 will be required for a central city branch for the immediate treatment of minor ailments and accidents. The annual expenditure of the new infirmary, the central branch, and a yearly contribution to the maintenance of the Barnes Convalescent Home at Cheadle is estimated at £34,500. The £400,000 from the corporation have been supplemented by some smaller sums and by generous contributions from private persons, so that the new infirmary is free from debt at this its most auspicious opening. The infirmary has given of its best, not only to Manchester and Salford, but to a district extending from Barrow in the north to Crewe in the south, so the area to which it may appeal in its turn is a wide one, and it may surely be anticipated that the whole district will help to maintain the new infirmary sufficiently well to enable it to continue its beneficent work.

The new Manchester Royal Infirmary consists of 48 separate blocks of buildings. The principal frontage is to the west, looking across Oxford-road to the Whitworth Park, on the north it fronts to Nelson-street, to the south is York-place, and there is a back entrance from a street on the east of the hospital.

Entering from Oxford-road the visitor finds in front of him a four-storeyed block with wings at each side, the administrative block, containing the offices of the general superintendent's department, a large board room, the resident medical officers' dining-room, the medical board room, and

Manchester Infirmary: Block plan standing on about 13 acres of land (reproduced from the prospectus of the institution the committee room. Residential quarters for the general superintendent, lady superintendent, and medical officers occupy the first and second floors, while those for the domestic servants are on the fourth floor. Three staircases provide for suitable division and for safety in case of fire. The flat roof can be used for a promenade. To the right, or south, is the nurses' home, and in the back sections are bedrooms and sitting-rooms for the ward-maids and laundry-maids. There is ample provision of bathrooms and lavatories. On the left is the teaching block, containing cloak-rooms and common rooms. A large lecture room and museum occupy the main part of the upper floors. The roll of names of the honorary staff from 1752 is recorded in the large entrance hall. Going east from the administrative block by the central corridor the storekeeper's department and the servants' hall and dining-room are on the left and right respectively, with the kitchen department above. The kitchen, 60 feet long by 35 feet wide and 29 feet high, is one of the finest rooms in the hospital, and is lined with glazed bricks. When the hospital is fully occupied meals for nearly 1000 people will be cooked, so that the large kitchen is necessary. There are no fires, for everything will be cooked by gas or steam. There are cold rooms for meat and milk, and all kinds of ingenious arrangements for doing work and saving labour. The food will be taken in special wagons along the covered ways, and up or down lifts as required to the different wards. The patients will all enter the hospital through the Nelson-street entrance. Out-patients will turn to the left, entering through a vestibule (seated for 60) the large waiting-hall, passing the hospital office, which is between the two. This hall is 92 feet long, 41 feet 6 inches wide, and 28 feet 6 inches high, and seats 400. It has a glazed lining and concrete floor and can be readily washed out by a hose-pipe and squeegees. The dispensary is at the end. There is a refreshment counter where a cup of tea, &c., can be obtained at a moderate charge. The consulting-rooms are at each side and there is a small operating theatre. Casualty cases are dealt with in a block to the right. Ambulances can be unloaded under cover on the level of the examination room. In the basement of this block are rooms for electrical and X ray work, massage, and medical baths. Above the casualty department are the gynæcological wards. In the centre of this block is the entrance to the in-patients' admission room, and at the south end of it are wards and an operating theatre for aural cases, while over them is a special ward for burns. A covered way along the side of this block, 756 feet in length, extends to the south boundary of the site, and from it two covered ways turn at right angles; to the east staircases from these give access to the wards above, the north to the surgical and the southern one to the medical wards, while branches to the west connect various blocks together. All the internal traffic of the hospital is under cover. The sides of these passages are enclosed to the height of four feet only, so that though they are protected from the weather by an overhanging roof the air has free access, and satisfies modern requirements as to free air spaces between each part of the hospital. Under the covered ways are subways in which all the principal heating, hot-water, steam, gas, and cold-water pipes are laid, and also electric mains and telephone wires, so that they can be attended to without interfering with the regular traffic of the hospital. The wards are on the pavilion principle, with spaces of 60 feet between them. Five of the ten pavilions are surgical, while four are devoted to medical cases. Five are of three storeys and the other five of two storeys, thus giving 25 large wards. Each pavilion runs north and south, and each large ward receives direct sunlight. The distance from the administrative centres of distribution is reduced to a minimum. The subdivision of internal traffic for goods and staff lessens noise and confusion. The distance from main thoroughfares, together with the intervening buildings, minimise external noise, and in this respect among others there is a great improvement on the state of things in the old infirmary at Piccadilly. Each pavilion has an open-paved basement and is separated from the ground. The wards are grouped in units. Each medical unit has two large wards on the same floor, one of 22 beds for males, and one of 18 beds for females, together with a few small wards, ward kitchens, store and linen rooms, two day-rooms, and *physician's room.* As pavilions run nearly north and south, the beds are on the east and west sides of the wards, and at the south end there is a balcony where, if the weather allows, the patients can enjoy the sunshine. The sanitary arrangements in the detached towers at the south-east and south-west corners deserve examination by experts. The wards are heated by hot-water radiators, and a supply of fresh air, regulated by a valve, enters at the back, is warmed by the hot surface of the radiator, and passes into the ward. On the sides where the male and female wards face each other a new window glass is used, which is transparent and smooth, and yet is sufficiently obscured. The floors have linoleum laid on the smooth concrete, and there are no square corners for the lodgment of dirt. The "Gilmour" doors, except where there are glass panels, are flat and smooth on both sides, and indeed every care has been taken that the environment of the patients should be absolutely cleanly. The surgical wards are similar to those on the medical side, but each of the five groups contains two male wards of 16 beds each and one female ward of 20 beds, while small one- or two-bed wards bring the total up to 60. A separate block to the north of the covered way contains the operating theatre and its accessories on the same floor. A small gallery for students is cut off from the operating part by a plate-glass screen seven feet high to interrupt dust, but not to prevent a clear view or the sound of the surgeon's voice. The theatre walls are lined with Sicilian marble to a height of seven feet, and above that with "reconstructed marble," and the ceilings are glazed with opalite. The floor is of "terrazzo."

The remaining buildings are the mortuary and pathological laboratory and lecture room; the isolation block for septic cases; the laundry; the lodges, in Oxford-road, Nelson-street, and Berlin-street; the matron's office; a residence for male servants; and a carriage shelter. Another building is the chapel, which will seat about 200. The drainage is divided into many sections, thoroughly ventilated, and the soil drains are flushed by rain-water, which is carried to the different flushing tanks. In this way the cost of flushing with town's water is avoided. The cold-water service is taken from three separate corporation mains, each of which can serve any part of the hospital, so that a breakdown in the supply can scarcely occur. In like manner the electric supply is taken from separate corporation generating stations to the main switch-boards, and the light in each pavilion is divided between the two separate sources of supply, so that a total failure of light is very unlikely to happen. Without going into tedious details, it is safe to say that all contingencies seem to have been foreseen and provided for. The amount of thought that has been given to the plans generally and to every conceivable arrangement for securing sanitary conditions throughout the whole of the buildings must have been enormous, and they represent the combined product of most acute and earnest minds directed to one object—that is, to the alleviation of the suffering and pain of the sick poor.

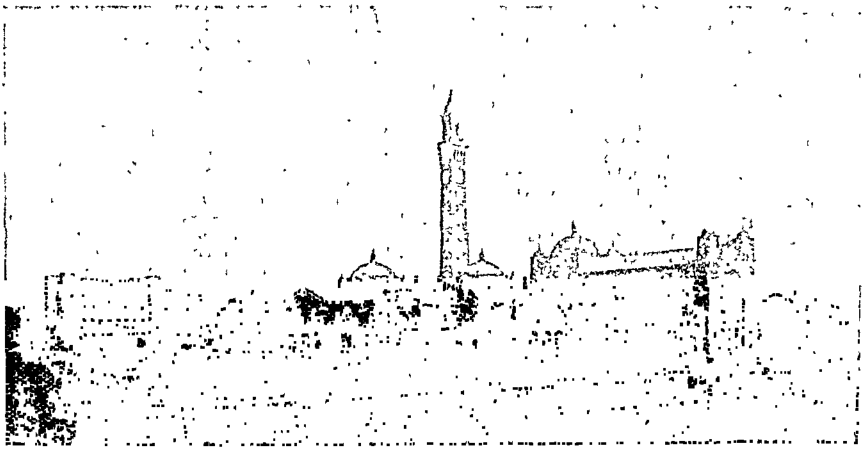
BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New Buildings of the University.

ONLY those who have seen the buildings, formally opened by the King on July 7th, have any idea of their magnitude or of the grandeur of the plan which is being gradually developed. The present buildings, magnificent in themselves and splendidly equipped, are even now in many respects unique, but when circumstances are favourable other blocks will be erected until the whole is complete and as near perfection as possible. For the present, equipment, endowment, and the extension of teaching and research are the foremost necessities, and the departments not yet provided for at Bournbrook must continue to work in their more or less cramped quarters in the old buildings; but the time must come ere long when it will be no longer possible to accommodate zoology, botany, geology, anatomy, and physiology in their present quarters, and money will have to be found for the erection of the additional blocks at Bournbrook, which will complete the original plan and furnish accommodation for the sciences which are so closely associated with those at present housed in the new buildings. There can be little doubt that eventually the various departments of the Faculties of

Arts and Commerce will also be transferred to Bournbrook. We shall then possess the beginnings of a university of which the Midlands may well be proud. It will possess imposing buildings surrounded by their own gardens and athletic grounds, and will be within easy reach of manufactories, mines, hospitals, and business establishments, where the practical application of scientific training can be demonstrated and studied. The interest already taken in the university by the people of the city and the immediate neighbourhood is indicated by the fact that during the last three days of the past week, when the new buildings were thrown open to the public, 155,000 people availed themselves of the opportunity to inspect the various laboratories and class-rooms.



Birmingham University: the Bristol-road façade. The central groups of buildings are the mechanical, civil, and electrical engineering laboratories. The building to the left is the chemistry school, and that to the right, beyond the great hall, is the mining and metallurgy laboratory. (Photograph supplied by Messrs. Whitlock.)

The Graduation Ceremony.

The graduation ceremony which took place in the town-hall on July 3rd was, as usual, an occasion for the display of pretty dresses and hats by the ladies, of wonderful and multi-coloured gowns by the graduates, and for the creation of much noise by the undergraduates. One of the striking features of the ceremony was the number of women graduates, who were especially numerous in the Faculty of Arts.

The Death of Professor Bridge.

Although the friends and colleagues of Professor T. W. Bridge had noticed with deep concern that he appeared to be far from well and was rapidly losing strength, nevertheless the somewhat sudden and fatal termination of his illness came as a surprise and a shock, for up to a comparatively recent date he had been taking an active part not only in the work of his own department but in connexion with the rearrangement of the curriculum necessitated by the removal of the schools of physics and chemistry to Bournbrook. He was a genial, helpful, and kind-hearted colleague who will be much missed by those with whom he has been associated for so many years, and particularly by the members of the Medical Faculty with whom he always had the most cordial relations.

The New Professor of Surgery.

Professor Jordan Lloyd's appointment to one of the chairs of systematic surgery will be very popular, for he is a great favourite with the students, whom he rules and guides with a strong hand, both in the hospital wards and the University classes. Hitherto he has been professor of operative surgery, but when Professor Bennett May resigned his chair of systematic surgery the council of the University requested Professor Lloyd to take the vacant place and he accepted the invitation, his acceptation necessitating the resignation of the position he previously held. His new appointment will give greater scope for his energy and ability, but it will also make much greater demands upon his already very fully occupied time.

Fire at the General Hospital.

Early on Monday morning last an outbreak of fire in the switch-room at the General Hospital was the cause of much inconvenience, but fortunately of only little damage. The first indication of anything wrong was given by a sudden flickering and then by the complete extinction of the electric lights. The men in charge, finding the outbreak in the switch-room, at once closed the lift and so cut off the basement from the hospital wards and corridors. On the arrival of the fire brigade the outbreak was soon extinguished, but the lighting could not be restored, so the buildings remained in darkness during the early hours before day-break, and as the electric fans were powerless the plenum system of ventilation had to be replaced by regulating the opening of windows.

The St. John Ambulance Brigade.

The members of the St. John Ambulance Brigade were much in evidence on the occasion of the King's visit to the City and University, and they performed a very useful function, which must otherwise have devolved upon the already overburdened police force, for they gave first aid to 563 cases, of whom about a dozen were removed to hospitals. Each member of the corps was equipped with complete first-aid dressings, and each squad of four men was supplied with a surgical haversack, a stretcher, and a squad water-bottle. The men looked smart, and they did their work quickly and well.

The Health of the City.

The cool weather of this remarkably sunless summer is proving beneficial to the public health. Our medical officer's last report shows that during the week ending July 10th the general death-rate fell to 10·6, the lowest rate recorded since August, 1907, and two lower than any rate recorded last year. The zymotic death-rate was 1·1. There were seven deaths from measles, and only one from scarlet fever.

July 13th.

A MEMORIAL TO SIR MORELL MACKENZIE.—The Leyton Urban District Ratepayers Association has arranged to affix a memorial tablet to the birthplace of Sir Morell Mackenzie, 742, High-street, Leytonstone, at the corner of Browning-road. The tablet will be unveiled on Monday, July 19th.

BRISTOL AND THE WESTERN COUNTIES.

(From our own Correspondent.)

The University.

The University machine is at work. During the past few days its principal governing bodies have met for the first time and transacted important business. On Wednesday, July 6th, the first court met; about 200 members were present, the Bishop of Hereford, as the oldest Pro-Chancellor, taking the chair in the absence of the Chancellor, Mr. H. O. Wills, through ill-health. Dr. Percival, in his opening remarks, spoke of the lasting indebtedness in which Bristol was placed, through its University, to the families of Wills, Fry, and Thomas. He gave a brief account of the developments which culminated that day in the court's meeting, developments which have been described in one of these letters. He reminded his hearers of the many great names which had already been associated with University College: Professor Marshall, Sir William Ramsay, Professor Sylvanus Thompson, Professor Sydney Young, and Professor Hele Shaw. Allusion was also made to the efforts of the Colston Society, and to the recently arranged union with the Society of Merchant Venturers. In concluding, he proposed 12 members of the court as representatives of that body upon the University Council. This proposal was seconded by the Right Hon. Henry Hobhouse, who spoke of the benefit which not Bristol only, but also the whole West of England, must hope to derive from the new centre of light and leading. The Right Hon. Lewis Fry moved that the seal of the University be affixed to an agreement with the Society of Merchant Venturers relating to the equipment and administration of the Faculty of Engineering. This motion was seconded by Mr. G. W. Davey, Master of the Society of the Merchant Venturers. The next motion was to the effect that all Members of Parliament for divisions of the counties or boroughs within the counties of Gloucester, Somerset, Wilts, Dorset, Devon, and Cornwall shall be members of the court. (The terms of the motion expressly excluded the Members for the four divisions of Bristol, who are *ex-officio* members of the court.) This was moved by Mr. M. W. Colchester-Wemyss, chairman of the Gloucestershire Council Council, and seconded by Mr. F. A. Hyett, chairman of the Gloucestershire education committee. Professor Turner brought a kindly message of greeting from the University of Oxford, and the Bishop of Bristol performed a like office on behalf of the University of Cambridge, and Professor Lloyd Morgan, Vice-Chancellor of the University, acknowledged the helpfulness of their words and of the support which the older universities had always been ready to give. He also remarked upon the existence of a Bristol medical school for many years before the foundation of University College. On Friday, July 9th, the Senate of the University met and elected six of its members as representatives on the Council. Two of these are professors in the Faculty of Medicine, Professor E. Fawcett (anatomy) and Professor J. Michell Clarke (medicine). Immediately after this the first meeting of the Council was held, the Right Hon. Lewis Fry being elected chairman. Professor Lloyd Morgan tendered his resignation of the Vice-Chancellorship, as he found the work belonging to that office so arduous as to hinder the prosecution of psychological research. Sir Isambard Owen, Principal of Armstrong College, Newcastle-on-Tyne, was appointed in his place. Other business transacted by the Council related to the transfer *en bloc* of the teaching staff of the University College to the University; to the formation of the engineering staff; to the purchase of Clifton Hill House as a hall of residence for women students; to the purchase of certain adjoining property; to certain matters relating to the purchase of the Blind Asylum premises; and to questions concerning the arms, seal, and mace of the University. Both in Senate and in Council motions were adopted appreciating Professor Lloyd Morgan's long and arduous labours on behalf of University education in Bristol. It is indeed a matter for deep satisfaction that the new University will still have his advice and guidance without prejudice to the scientific investigations by the fruits of which he will doubtless contribute yet further to its lustre as a seat of learning. The University will be universally felt to be fortunate in securing so distinguished a successor to the important office of vice-chancellor, the academic head. Sir Isambard Owen's experience in the development of universities is very great. He was instrumental in the foundation of the University of Wales, of which he is Deputy Chancellor, and since that time he has been actively concerned in the reconstruction of the University of Durham. His appointment to the Bristol vice-chancellorship is to date from Sept. 9th.

The Hospital Sunday Fund.

The final report of the council shows that the total sum collected for the past year is £1898 17*s.* 4*d.*, an increase of £39 10*s.* 6*d.* upon the previous year. Of this total, £1817 4*s.* 8*d.* have been distributed, the principal grants being £739 10*s.* to the Royal Infirmary, £620 10*s.* to the General Hospital, £239 10*s.* to the Children's Hospital, and £110 10*s.* to the Eye Hospital.

The Late Mrs. Markham Skerritt.

By the will of Mrs. Markham Skerritt, who died recently, the Bristol General Hospital receives £1000, the Bristol Blind Asylum £1000, and the University £1000 (less any sums paid during her lifetime) towards a fund for the establishment of a "Markham Skerritt" chair of Anatomy. Mrs. Skerritt, who was blind, survived her husband by about two years, their only child (a daughter) having predeceased her parents.

A Medical Officer of Health for Somerset.

At a meeting of the Somerset county council held last week it was decided by a large majority to adopt the recommendation of the sanitary committee and appoint a medical officer of health for the county who should also act as chief medical inspector of schools. The salary will be £700 per annum, rising to £800 by yearly instalments of £20, this remuneration to be exclusive of reasonable travelling and office expenses.

The Exeter City Asylum.

The annual report of the visiting committee of the Exet City Asylum, which has just been issued, states that durin 1908 448 patients had been under treatment, and that 33 remained in the institution on Dec. 31st. During the yea there had been 88 discharged and 33 deaths. The financi statement was satisfactory and showed that there had bee a profit during 1908 of £1394, which had been paid to th borough fund of the city.

The Sewage of Bath.

At a meeting of the Bath city council held on July 6t the sewage disposal committee recommended the council apply to the Local Government Board for sanction to borro £215,000 for new sewerage, pumping station, and main ar disposal works. This will provide for the sewage of population of 80,000 inhabitants. After some discussi the report was adopted with only three dissentients.

The Western Consumptive Hospital, Torquay.

It has been decided to carry out extensions at the Wester Consumptive Hospital, Torquay. The cost of the undertakin will probably be about £2000.

Witchcraft in Somerset.

At a conference of teachers held at Bury, near Dulverto on June 26th Mr. G. F. Sydenham in an interestin paper stated "that herbalists and white witches were stil living among them, to say nothing of 'The Doctor' o seventh son. The belief was widely held that whooping cough could be cured by placing the sufferer on th ground in a sheep-fold; epilepsy by procuring silver coin from friends and having them made into a necklace o bracelet to be worn by the sufferer; and hæmorrhage an burns by the chanting of a strange prayer. A seventh son, especially if he were the seventh son of a seventh son, was as much sought after in some parishes as if he were a Harley street specialist. His patients were attended on Sunday mornings after fasting, the cure being by touch and prayer."

July 13th.

LEEDS.

(From our own Correspondent.)

Death of the Marquess of Ripon.

By the death of Lord Ripon Yorkshire has lost one of her most eminent sons and the University of Leeds its first Chancellor and its most loyal and consistent supporter. It would be difficult indeed to think of any movement concerned with the University or with the steps that led to its institution, which was not a matter of deep concern to Lord Ripon, and which his ripe judgment and energy did not help to carry to a practical issue. He was among the number of those who assisted the Yorkshire College at its very commencement, and on the death of Lord Frederick Cavendish he was selected as Principal of the Yorkshire College. A generous donor to the funds of this educational institution, he did more than merely give money. Of his best energies he was lavish, and he must ever stand out conspicuous even among the many who have helped to bring about the realisation of the dreams and hopes of those in Leeds interested in University development.

Health Congress in Leeds.

For some time it has been felt that the holding of two simultaneous annual congresses, one connected with the Royal Sanitary Institute and the other with the Royal Institute of Public Health, was leading to a form of division of labour which was antagonistic to real work. Happily, as the result of mutual discussion, these two associations have accepted the invitation of the City and University of Leeds to hold a joint congress in Leeds in place of the usual two. So far as can be gathered the meeting is likely to be very successful. The Congress is fortunate in having as President, in the person of Colonel T. W. Harding, a former Lord Mayor of Leeds, a sanitary expert, an admirable chairman, and a man of wide culture and public spirit. On Monday, July 19th, the Lord Mayor, Alderman F. J. Kitson, will preside over a conference of municipal representatives and sanitary inspectors within the walls of the University, and a joint meeting will be held of the sections of bacteriology and chemistry and engineering and architecture. During the rest of the week there will be numerous sectional meetings concerning which some deta [illegible] your columns. The section [illegible] presided over by Dr. Arthur Newsholme, of the Local Government Board. On Wednesday morning an address will be given in the University by Dr. G. Newman, principal medical officer of the Education Department, and in the evening Sir C. A. Cameron, C.B., will give a lecture with experiments on "Ground Air." On Thursday Dr. B. A. Whitelegge, chief inspector of factories, will give an address on Industrial Hygiene. In the section on preventive medicine discussions will be held on the prevention of tuberculosis, the protection of food-supplies, on hospitals and segregation, on infantile diarrhœa, and on the educational aspects of a municipal milk-supply. The section on child study will be presided over by Sir James Crichton-Browne. Mr. William Hall, who, during the last few years, has supplemented the work of his long experience as a practitioner and inspector of factories by devoting a large amount of his leisure to the work of the feeding of children, will read a paper on the bearing of diet on the physical development of Aryan and Semitic children born and bred in Leeds. Professor A. S. F. Grünbaum, who presides over the section of bacteriology and chemistry, will give an address on his subjects, entitled "Ramparts of Health." A reception will be held in the Art Gallery by the Lord Mayor and on Monday the University holds a conversazione in the building of the medical school. On Saturday a congregation of the University will be held for the purpose of conferring honorary degrees on Colonel Harding, on Sir James Crichton-Browne, and on Major Ronald Ross, C.B.

July 13th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New Out-patient Department at the Royal Infirmary: Laying the Foundation Stone.

THE Earl of Derby laid the foundation-stone of the new out-patient department of the Royal Infirmary on July 7th, in the presence of a distinguished gathering, when the chair was occupied by Sir William Tate. Prior to the ceremony his lordship was presented by Mr. Ralph Brocklebank, the chairman of the committee, with a silver trowel. At the close of the proceedings visitors were invited to inspect the hospital and to partake of refreshment in the entertainment room. In architecture and material the new building will closely resemble the hospital. On the ground floor ample and suitable accommodation will be provided for medical and surgical patients. The large hall, 75 feet by 35 feet, open to the top, will have seating accommodation for 250 people. On the first floor provision will be made for the special departments—women, eye, throat and ear, and in the basement for venereal, skin, and massage departments. The committee is of opinion that everything desired for the efficient and economical working of the department will be secured. The accommodation set free in the present building will be most advantageously utilised for the reception of casualties and the provision of special beds, which are urgently needed. Although the cost of the bare fabric is assured, £25,000 having been already promised or subscribed, there is still a great deal of money to be raised to complete the work, which is estimated to cost about £30,000. The cost of maintenance is another item which will have to be faced by the committee. The average number of out-patients treated at the Royal Infirmary during 1908 exceeded 80,000, the work being much handicapped owing to the inadequacy of space available in the infirmary. It is estimated that the maintenance of the new out-patient department will require a sum of £1500 a year.

The University of Liverpool: Degree Ceremony at St. George's Hall: Ex-officio Degrees.

Following upon the results of the University of Liverpool examinations recently announced, the ceremony of conferring degrees upon the successful students took place on July 10th, at St. George's Hall, in the presence of an audience which was both numerous and representative. The function was performed by the Earl of Derby, the Chancellor of the University. It is interesting to note that amongst the recipients of *ex-officio* degrees were Mr. William Thelwall Thomas, associate professor of surgery at the University, and Mr. Robert Jones, surgeon to the Royal Southern Hospital, each receiving the degree of Master of Surgery.

July 13th.

NEWCASTLE-UPON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Durham University College of Medicine.

THE question of the constitution of the College of Medicine has been discussed on former occasions in these columns, and it is interesting to note the completion of the adopted scheme for reconstruction in the occurrence of the first meeting of the Court of Governors of the College on July 7th. The management of the College is now to be vested in three bodies—viz., the Court of Governors, the Council, and the Academic Board. The Court of Governors consists of elected, representative, and contributory governors, and at present numbers between 70 and 80. The Council, which has charge of the executive work, is made up of seven members elected by, and out of, the Court of Governors, seven from the Academic Board, and seven more—two representing the Senate of the University, the principal and two members of the council of Armstrong College, and two representatives of the house committee of the Royal Victoria Infirmary. The representative governors are sent from the various municipal, educational, and other authorities in the district. The Academic Board is made up of the professors and lecturers of the College, and its functions are purely educational and disciplinary.

Amongst those present at the court were Professor Sir George Hare Philipson (President of the College), Professor Sir Thomas Oliver, Professor R. P. Ranken Lyle, Professor R. Howden, Professor H. J. Hutchens, Professor Phillips Bedson, Professor H. Stroud, Dr. David Drummond, Dr. A. J. Collis, Dr. C. R. Stewart, Dr. J. T. Merz, Mr. J. Rutherford Morison, Mr. Cecil Cochrane, Mr. A. F. Ericsson, Mr. R. E. Lambton, and Alderman Newton. Sir G. H. Philipson was unanimously elected chairman, and Councillor W. J. Sanderson vice-chairman; Mr. Cecil Cochrane was appointed treasurer of the College, and the following governors were elected to sit on the council:—The Very Rev. the Dean of Durham (warden of the University), Lord Ravensworth, Professor Bedson, Mr. C. A. Cochrane, Alderman J. Cromie, Mr. J. E. Gibson, and Dr. Clement Stephenson.

It may be of interest to give briefly the progress of the College and the reasons for changing its constitution. The medical school was founded in 1832 and was called the Newcastle-on-Tyne School of Medicine and Surgery, and the work was carried on in two rooms—one for the lectures and a small one for the lecturer's use. The first lecturers were George Fife, John (afterwards Sir John) Fife, Alexander Fraser, Samuel Knott, and H. G. Potter. The number of students on the first register was eight. The number of the teaching staff has now reached four times that of the commencement and the students on the register last winter were 202. During the first 20 years of its existence the school was not in connexion with the University of Durham and students had to take up residence at Durham in the University in order to proceed to a degree in medicine at the University. In 1852 new arrangements were made by which attendance at the school in Newcastle was considered as equivalent to residence at Durham (for the purpose of the medical degree), and so a great difficulty for the student was removed. Up to the present time the business and other affairs of the College have been arranged by a council consisting of the professors and lecturers with three representatives of the Senate of the University, the addition being made a couple of years ago of several prominent public men. In spite of this, however, it was felt that the public and the public bodies should be brought more closely into touch with the College and its administration, and the scheme which has now been adopted was broached. It remains to be seen, of course, what the results may be, but there can be no manner of doubt as to the wisdom of such a step. The mode of representation on the Court of Governors has been carefully dealt with so as to be representative of all the educational and other authorities in the city, more especially of the Armstrong College, where the first year medical student takes out most of his classes, and the Royal Infirmary, where his clinical work is done in the third, fourth, and fifth years. Under the old constitution the College has had a markedly successful life, and it is hoped that the innovation in the management may lead to even better work.

That the school has many advantages can be seen from its geographical situation between Leeds and Edinburgh, the enormous opportunities for clinical work in a general hospital which drains a large area; further, the reports of the inspectors of the General Medical Council state that the examinations of the University of Durham are of a high standard; and finally, the increasing number of the students is an excellent indication. Altogether it is a most desirable thing to incorporate the representatives of the various public bodies and prominent laymen, for after all it is from the layman that real support of every kind must eventually come, and there has latterly been some little tendency for the training for the high profession of medicine to be neglected as opposed to the support given to purely technical instruction, as judged perhaps by the more immediate results derived from the support of the latter.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Finlayson Memorial Lectureship.

Sir Hector C. Cameron, on behalf of the committee of subscribers to the fund in memory of the late Dr. James Finlayson of Glasgow, has presented a deed of gift to the Council of the Faculty of Physicians and Surgeons of Glasgow, conveying to the Council the future management of the fund. The income from the fund is to be held and applied as the endowment of a lectureship to be called "the Finlayson Memorial Lectureship." The selection of lectures is vested in a committee consisting of the president, the visitor, the honorary librarian, and the honorary treasurer of the Faculty for the time being, the present professors of the practice of medicine and of pathology in the University of Glasgow and their successors in their present chairs, and Dr. Andrew Freeland Fergus, who was closely associated with the movement in favour of the fund. The lectures are to deal with some part of pathology or the practice or history of medicine, and will be duly advertised. They will be delivered in Glasgow, possibly every third year, but at least every fifth year, and will be open to all registered medical practitioners and such other persons as the Council of the Faculty may think proper. The first lecture under the management of the original committee was given in February, 1908, by Dr. Norman Moore of London, who lectured on the "Schola Salernitana," its History, and the Date of its Introduction into the British Isles.

Death of Dr. T. Brown Henderson.

The death took place last week of Dr. Thomas Brown Henderson, one of the oldest medical practitioners in Glasgow. Dr. Henderson, who had reached his eighty-first year, was well known among the members of the profession and in connexion with several philanthropic institutions, with the work of which he was for many years closely identified. He was a native of Lanarkshire, and so long ago as 1851 he qualified as a Licentiate of the Faculty of Physicians and Surgeons of Glasgow. Three years later he became a Fellow of the Faculty. His medical studies were continued at the University of Aberdeen, where he graduated M.B. in 1856, and two years later took the degree of Doctor of Medicine. A few months ago Dr. Henderson was laid aside owing to illness, and, though he partially recovered, his health was seriously impaired. Among the institutions and movements of a philanthropic character with which Dr. Henderson was more intimately associated were the Glasgow Dental Hospital, Ear Hospital, and Medical Mission.

Management of Ruchill Fever Hospital.

More than a year ago it will be recollected that owing to reports of overcrowding and also of friction between the members of the staff in Ruchill Fever Hospital a commission was appointed by the Local Government Board to inquire into the state of matters. The commission made several suggestions to the health committee of the corporation with a view of putting things on a more satisfactory basis. Since that time some have thought that friction still continues, and recently a petition signed by 18,000 citizens was presented to the corporation "to appoint an independent inquiry into the administration of the Ruchill Hospital from the date of the Local Government Board inquiry up to the present date, and requesting that the parties carrying out the said inquiry consist of citizens from the following bodies—viz., three from the Faculty of Physicians, three from the Faculty of Procurators, three from the Merchants' House, and three from the Trades Council, with a neutral chairman." A special committee was appointed by the corporation to consider the petition. The committee has now made its report and directs attention to Section 5 of the Public Health (Scotland) Act, 1897, under which the Local Government Board for Scotland is constituted the central authority in respect of all matters affecting public health, including the administration of infectious disease hospitals. The committee therefore has recommended that the petition be transmitted to the Local Government Board.

Death of Dr. Robert Morrison, Methlick.

The announcement of the death of Dr. Robert Morrison of Methlick will be received with very sincere regret by all who knew him. Dr. Morrison, who belonged to the New Deer district, was in early life associated with farm work. He afterwards studied medicine at the University of Aberdeen and graduated M.B., C.M. there in 1887. Subsequently he started practice in Methlick and very soon gathered together a very large practice. Of a retiring disposition, he was yet ready at all times to render assistance ungrudgingly, taking a keen interest in all that pertained to the welfare of the neighbourhood. As a member of the School Board he rendered good service, and he was also a punctual office-bearer in the parish church. His widow and family will have the sympathy of the entire community.

The Medical Inspection of School Children: Scheme for the County of Aberdeen.

A meeting of the Aberdeenshire secondary education committee was held on July 9th, when a sub-committee submitted a scheme for the medical inspection and supervision of school children under the Act. The scheme suggested a practical amalgamation with the public health department of the county, Dr. Watt being appointed as chief medical officer. The committee, however, did not accept this scheme and resolved to appoint a chief inspector with a salary commencing at £300 and rising by annual increments of £20 to £400. It was also resolved to appoint an assistant at a salary commencing at £200, and rising by annual increments of £25 to £300. This scheme will be submitted to the school boards in the county and to the Scotch Education Department. A conference of the school boards will be called to consider the proposal after it has been circulated.

The Sidlaw Sanatorium: Annual Meeting.

The annual meeting of the directors of the Sidlaw Sanatorium was held on June 29th. The directors in their ninth annual report stated that it was disappointing to the directors to find that the claims of the institution, which the citizens of Dundee at its opening agreed to maintain, were not being met, and that the year's working showed a deficit amounting to £309 7*s*. Dr. A. K. Traill, the medical superintendent, in his report stated that he had endeavoured to trace those patients who had been discharged with the disease arrested since the opening of the sanatorium. The following table showed the after-results in those cases whose history he had been able to obtain:—

	Alive.	Dead.	Working.
Year ending April 30th, 1904	5	5	5
" " " 1905	10	7	10
" " " 1906	25	10	22
" " " 1907	23	5	20
" " " 1908	37	0	32
" " " 1909	37	0	33

The Lord Provost, in moving the adoption of the report, referred to the intentions of the late ex-Provost Moncur in founding the institution. It was perfectly evident, continued the Lord Provost, that the conditions on which Mr. Moncur's gift was accepted had not been carried out by the citizens of Dundee. It seemed to him that the only hope of the good work being continued was cooperation with the public health authority in Dundee. With this object the town council had appointed a committee to consider how the public health authority could work in conjunction with the directors and supply a sufficient number of selected cases paid for from the public rates. The report was unanimously adopted.

July 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Increase of a Dispensary Medical Officer's Salary.

IT is gratifying to be able to call the reader's attention to an act of relative generosity to a dispensary medical officer, coming from a board whose conduct in the treatment of another has been criticised rather severely. At the weekly meeting of the Castlerea board of guardians on July 3rd a motion to increase the salary of Mr. P. C. Walsh was brought up for discussion. Mr. Sweeny, whose notice of motion had been placed before the board a fortnight previously, pointed out that not a single complaint had been lodged with that board during the whole period of Mr. Walsh's 30 years of service. The seconder of the motion pointed out that Mr. Walsh's work was not confined to one district of the union, but was spread over the whole; while some of the worst cases were brought in there for treatment. The general good feeling of the meeting was soon shown in the fact that although, as was to be expected, one member tried to cut down Mr. Sweeny's proposed increase (£30) of salary to £20, the half-way sum of £25 was unanimously voted. Those who know the district know how thoroughly Mr. Walsh deserves his popularity.

Belfast and the New Tuberculosis Act.

At a recent meeting of the Public Health Committee of the Belfast corporation the medical officer of health submitted a report dealing with the new Tuberculosis Ireland (Prevention) Act which came into force on July 1st. He thinks the prescribed circumstances and the prescribed form of tuberculosis to be included in the compulsory notification of this disease, as now defined, are of too limited a nature, surrounded with restrictions, and dependent on the discretion of those in attendance, so that they may lead to disappointment. Many persons hold this view. But I may recall the fact that the cases to be notified are those of tuberculosis of the lung "so circumstanced that they are likely to prove a means of distributing the disease unless precautionary methods are adopted." He thinks, owing to the limited scope of the Act, that if adopted in Belfast there will only be obtained by the Act of Parliament what is already obtained voluntarily through the action of the dispensary medical officers of Belfast in notifying all cases of phthisis admitted to the Belfast union. A further source of information available to the Belfast health authorities was supplied by persons seeking admission to the corporation beds in the Forster Green Consumption Hospital. Now, in reply, it may be said that there are only 14 dispensary medical officers in Belfast, a city with a population of 370,163 inhabitants, and 30 beds alone available for the corporation at the consumption hospital. The medical officer of health thinks the fact that 1213 cases were dealt with during the past year shows that these two sources of information have been productive, but if we turn to his last report—that for 1907—we find that 926 deaths occurred from phthisis and 469 from other forms of tuberculosis—that is, 1395 in all. Now, taking the phthisis cases alone (926 deaths) and multiplying them by ten to arrive at the number of living persons suffering from the disease, which I consider is a very moderate estimate, it would show 9260 patients with active pulmonary tuberculosis, and yet according to this scheme of voluntary notification in Belfast only 1213 were dealt with. The medical officer of health further objects to the expense in working the Act. He says that during the years 1899–1908 the average number of deaths registered as having been caused annually by this disease was 1054, and that the fees alone for the first year, provided all cases were notified, would amount to £1317 10*s*.; further, there will be the expense due to an increased clerical and sanitary staff. The medical profession is to be paid for doing work in regard to an infectious disease—phthisis—as it is with regard to any other notifiable malady, and the stamping out of a disease which alone causes more deaths than all the other infectious zymotics put together is a work of true economy. If the medical officer of health could see his way to advise his committee to adopt the Act, and proceed gradually to put its clauses into work, we might hope to see some improvement in dealing with a disease which has an appalling influence on the death-rate of Belfast.

Whiteabbey Sanatorium.

At a meeting of the Belfast board of guardians held on July 6th the best thanks of the guardians were voted to Mr. Robert Hall "for the manner in which he had conveyed to the guardians such a clear and accurate account of the work done by the medical and nursing staff of the sanatorium during the past half-year."

The late Thomas McIlroy.

Deep regret is expressed in the surrounding district at the death of Dr. Thomas McIlroy, which occurred in sad circumstances at his residence at Newtownards on July 6th. When cycling home on the evening of July 2nd, after visiting a patient in the county, a collision took place with a horse and trap, the result being that Dr. McIlroy was thrown violently to the ground and received a transverse fracture of the skull. He was at once rendered unconscious and remained so until hi[illegible] at Queen's [illegible] University [illegible] L F P.S.G. [illegible] about 29 years ago, and while residing there he had by his skill, extreme amiability, and genial disposition built up a large practice which included many of the leading families in the district. He was deeply interested in every movement that had as its object the advancement of the interests of Newtownards. He was medical attendant to the police and to the Post Office officials, and was civil surgeon to the troops of the 4th Battalion of the Royal Irish Rifles. He was buried at Movilla Cemetery on July 8th. Much sympathy is felt for his widow and only child, Mr. Hugh McIlroy (who is a promising medical student), in their great trial and bereavement.

July 31th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

International Congress of School Hygiene.

THE Third International Congress of School Hygiene will meet in Paris during Easter week in 1910—namely, from March 29th to April 2nd. All civilised countries have formed committees and will send representatives. It is evident that the movement for improving the hygienic conditions of primary and secondary schools (*de l'école et du lycée*) will become important. There will be three discussions and 30 papers read in the sections by French and foreign contributors. Inquirers can obtain full information from the general secretary, M. Dufestel, 10, Boulevard Magenta, Paris.

Traumatic Detachment of the Superior Maxilla.

At a meeting of the Surgical Society held on June 23rd M. Ferraton described two cases of fracture (*fracture par disjonction*) of the superior maxilla in which this bone was completely separated from its osseous attachments. The cases came under his notice last year; in each of them the injury had been caused by the kick of a horse, and the detachment of the superior maxilla was as complete as if a surgical operation had been performed for its removal. This lesion required for its production a very violent blow directed obliquely on the lower portion of one of the maxillary bones near the dental arches. Consolidation of the bones was followed by stricture of the lacrymal canal. The diagnosis was obvious and the displacement was easily reduced under an anæsthetic, but it returned immediately if a fixation apparatus was not applied.

Toxicity of Cancerous Extracts.

At a meeting of the Society of Biology held on June 26th Madame Girard Mangin showed that toxic substances were present in cancerous extracts obtained from tumours which had not undergone suppuration and were treated aseptically; the tumours in question occurred both in the human subject and in the lower animals, and moreover grew both in epithelial structures and in the connective tissue. These toxic substances reduced the blood pressure and the body temperature; they might produce paralysis, and when administered in fatal doses they gave rise to convulsions. They generally caused death by stoppage of the respiration, the heart continuing to beat. Animals which did not yield at once to the action of these cancer toxins became ill and died in a state of profound anæmia without appreciable lesions. The toxic qualities of these extracts were, she thought, more useful than histological examination in elucidating clinical phenomena.

Treatment of Acne Rosacea.

At a meeting of the Société de l'Internat des Hôpitaux de Paris held on June 24th M. Jacquet described the case of a man who had for 20 years suffered from acne rosacea in a form so incredibly severe that the skin of his face became converted into a kind of sponge containing pus. Under appropriate treatment he completely recovered in two months. His habitual dietetic system was anything but conducive to health, for he drank much wine, ate hurriedly, was partial to acid substances, and read during meals. Massage of the face was ordered and in some weeks he was not only freed from the acne but was also no longer troubled as before with dyspepsia, giddiness, and transient disorders of vision.

Some Effects of White Swelling of the Knee.

At a meeting of the Society of Paris Surgeons held on June 18th, M. Barbarin said that the abnormal alignment of the leg in white swelling of the knee was often due to hyperplasia of the femur and the tibia, especially at the level of the epiphysis. This hyperplasia extending to the whole epiphysis caused lengthening of the limb and distortion on flexion. If it was localised in the internal condyle it caused genu valgum. These deformities were usually transient, and the examination of them must include radiographic inspection as well as the noting of clinical details. Conservative treatment gave excellent results if it was gentle, continuous, and not based upon a vain expectation of rapid recovery. In white swelling of the knee the power of movement ought to be regained, he thought, in about 50 per cent. of the cases under well-devised treatment.

Congress of Social Hygiene.

A Congress of Social Hygiene met at Agen on June 25th, M. Jules Siegfried, vice-president of the committee of social hygiene, being in the chair. M. Siegfried spoke of the benefits resulting from what had been done for the promotion of public hygiene and morality; he also referred to the advantages of domestic sanitation as carried out by the English and Americans.

Mercurial Stomatitis caused by Grey Oil.

At a meeting of the Société Médicale des Hôpitaux held on June 18th, when cases of severe stomatitis were being discussed, M. Gauchen spoke of the dangers of grey oil and recommended the use of soluble salts of mercury. M. Balzer said that the danger was due not to the grey oil but to the wrong use which was made of it. Some practitioners injected it in such large doses (*par centimetres cubes*) that accidents were to be expected. Using it with prudence M. Balzer had not seen any ill-effect during the last 25 years. He no longer employed calomel because it caused pain, but grey oil was not open to this objection. M. Mosny said that bottles (*ampoules*) of grey oil, each containing 40 centigrammes of mercury, were on the market—a detestable system, for some practitioners believed it necessary to inject the entire contents of a bottle at once with the result that the patient suffered from mecurial poisoning. M. Queyrat said that he had already pointed out the danger of this mode of treatment; he had, however, used grey oil without accident for many years and was quite satisfied with it.

The Casimiroa Edulis, a New Hypnotic.

At a meeting of the Therapeutical Society M. A. Robin and M. Cayon have communicated the results of their investigations on the Casimiroa edulis or *zapote blanc*. This plant, which belongs to the rutaceæ, was, they said, an excellent hypnotic. When the hydro-alcoholic fluid extract of the seeds was given in doses of one or two teaspoonfuls it produced two or three hours afterwards a natural sleep lasting from five to six hours and not followed by headache or a sensation of fatigue. Being harmless, it might be given to aged persons suffering from renal troubles and it would be very serviceable in nervous diseases. Pathological alterations of the muscular fibre of the heart contra-indicated it.

Treatment of Intermittent Claudication.

At a meeting of the Academy of Sciences M. Moutier pointed out recently that sclerotic lesions of the arteries of the lower limbs might cause two kinds of morbid phenomena. If the ischæmia was incomplete the result would be intermittent claudication, a purely functional disorder long known in the horse but first described in the human subject by Charcot. If the ischæmia was complete the result was gangrene, almost always preceded by intermittent claudication. M. Moutier has seen several patients, some in the stage of claudication and others more advanced, in whom the use of d'Arsonvalisation, either local or general, brought about a considerable and permanent improvement. In particular, one patient who was the subject of arteriosclerosis recovered from an early stage of gangrene of both feet.

Women and the Bachelor's Degree.

The Superior Council of Public Instruction has recently rejected a motion to exempt women desirous of following medicine or pharmacy from taking their bachelor's degree Their exemption from military service already places women at an advantage, against which a good many medical students and practitioners are beginning to protest. It has even been suggested that the two years of military service should be replaced by two years of some such employment as sick nursing, which should be compulsory to medical women, either during their student days or after their qualification.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Conditions Predisposing to Longevity.

Dr. v. Lindheim, a writer well known for his researches on sociology and on what may be called "folk-medicine," recently communicated to the Gesellschaft der Aerzte the results of his observations on a series of 700 persons of both sexes, who had reached the age of 80 years and upwards This memoir, which has now been published in a separate form, appears to be the most exhaustive investigation of its kind on the subject. The occupation, the religious persuasion, and the family history of the individual are given in each instance. His observations have led Dr. Lindheim to the conclusion that instances of longevity are most often met with among persons who have been born in wedlock; whose parents and grandparents have been healthy, and especially if they have been long-lived; who have in infancy been breast-fed either by the mother or by a wet-nurse; who have studied regularity, punctuality, and temperance all through life; and who have postponed their retirement from active occupation as long as possible. Length of life is, as a rule, independent of wealth, for luxury and ease are more fatal than poverty; it is also immaterial whether the persons have resided in a town or in the country, or whether they have passed through illness and sorrows, if their disposition did not lead them to brood over them. The eye was of importance in the causation of longevity because loss of sight tended to shorten life by unfitting a person for work, which was the chief factor in longevity. As regards nutrition, a mixed diet was the best; alcohol and tobacco in small quantities have not been found to be detrimental to the attainment of old age, but rather the contrary. Dr. Lindheim has also shown that amongst those who were recognised as talented individuals and leaders of mankind there was an unexpectedly large number of old persons. Old age must therefore be credited with a fair amount of productive activity; many most important public performances have been accomplished by persons more than 60 years old; poets, artists, generals, men of science, politicians, and inventors have seen three score and ten years before reaching their zenith. The suggestions thrown out by Dr. Lindheim are worth mentioning. As paramount importance attaches to the lineage of an individual, medical practitioners ought to be consulted before marriage; a certificate of health ought to be furnished by each of the contracting parties; matrimonial transmission of syphilis or gonorrhœa ought to be made punishable; healthy persons in the poorer circles should have inducements to marry and rear healthy offspring; and breast-feeding should be encouraged by awards and the protection of mothers. The age for compulsory retirement from active work ought to be made higher than at present, unless in case of illness. Dr. Lindheim says that retirement from active work, whether compulsory or prompted by indolence, means a loss for the State and premature death for the individual.

Cremation in Austria.

The progress of cremation in this country is far from satisfactory from a medical point of view. There is a society here called "Flamme" (Flame) which seeks to promote this idea, but the number of its members is less than 300, and it has not yet been found possible to establish a crematorium in Vienna, although there are two in other parts of Austria. There is, however, a small, though constant, increase in the number of persons who, in their wills, order the cremation of their remains. Last year 115 bodies were sent from Vienna to Graz for this purpose. In spite of medical remonstrances, when the subject was discussed in Parliament, ecclesiastical reasons were brought forward in opposition, and whenever such arguments are adopted, then, in this country, they are victorious. At one of the last medical exhibitions the "Flamme" had a series of exhibits to show the advantages of cremation in comparison with interment, both from the practical and the sentimental point of view. The appearance of a corpse disinterred after the lapse of a period between one and three years, and consequently exhibiting the process of slow decomposition was gruesome enough when compared with the unobjectionable condition of the ashes preserved in urns. A prize has been offered by the "Flamme" for the invention of an apparatus for rapid and economical cremation; a reduction of the rates charged by burial grounds for the urns containing the ashes of the dead has also been applied for but in vain. A "travelling school" has, however, been recently established for the purpose of popularising the facts which are in favour of cremation, and as no obstacle has been placed in its way by the local authorities the result will perhaps be satisfactory. Needless to say the fees at present charged are too high to make cremation possible among the poorer class of the population.

The Indications for Cæsarean Section in Placenta Prævia.

At a recent meeting of the Obstetrical Society of Vienna there was a discussion on the value of Cæsarean section in cases of placenta prævia. Dr. Novak reported from Professor Rosthorn's clinic that in the last seven years there were 237 cases of placenta prævia in which 5·9 per cent. of the mothers and 80 per cent. of the children died. The methods adopted (combined version, without extraction) accounted for the high death-rate of the infants. The results in private practice, however, were excellent, only 2 per cent. of the mothers and 38 per cent. of the children dying in connexion with parturition. The reasons for this were that the surroundings were better and there was an earlier resort to medical help than among those classes who apply to the hospitals. The results of the purely obstetric methods were so favourable in expert hands that they could hardly be improved by Cæsarean section. Professor Schauta in examining the records of 54,000 cases of labour found 438 cases of placenta prævia, with a maternal mortality of 7 per cent. and a fœtal death-rate of 57 per cent. Among all these cases there were only 88 (cases with complete placenta prævia) which would have been deemed suitable for Cæsarean section, while of these only 25 women could be considered uninfected and it would be highly dangerous to undertake the operation in an infected woman. Of these 25 cases four died, all of them from hæmorrhage; they had been brought to the hospital almost exsanguine. The remaining 21 were delivered by ordinary methods and survived the labour. Thus it would appear that Cæsarean section could not have reduced the maternal mortality. Moreover, as the majority of the children were under the normal weight, even the infantile mortality would hardly be diminished by the operation. Professor Schauta would restrict Cæsarean section in placenta prævia to cases where the patient had not had hæmorrhage, had not been examined outside the clinic, and was pregnant with a healthy full-term child. Amongst the immense collection of 54,000 cases he could not find even one complying with these requirements. Similar experiences were reported by Professor Porkacek, Professor von Rosthorn, and others. The agreement between the speakers, who are connected with the largest obstetric clinics in Vienna and perhaps in Europe, is of special interest on account of their great experience and the enormous material for evidence at their disposal.

July 12th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Deaths from Poisoning in Bengal; Analysis of Water and Milk.

THE prevalence of poisoning cases in Bengal is prominently brought to notice in the annual report of the Chemical Examiner to the Government for 1908, which has just been issued. The viscera of no fewer than 770 persons suspected of having been poisoned were chemically analysed during the year, and poison was detected in 317 cases, this proportion being equivalent to 41·17 per cent. and 38·57 per cent., as compared with the year preceding. Opium was, as usual, the poison most generally used, arsenic being next in frequency. Of the 133 samples of drinking-water received from jails, municipalities, and other departments analysed during the year, 3 were classified as "good," 93 as "usable," 18 as "suspicious," and 19 as "impure." As regards milk, 18 samples were analysed, and of these 11 were found to be of good quality and 7 to be diluted with water.

The Viceroy of India.

The Viceroy and Lady Minto completed their Pasteur treatment on May 28th. Their Excellencies have not suffered in general health.

Illness of the Amir.

The Amir of Afghanistan, who has lately been suffering from gout, having derived but little relief from the ministrations of the Kabul hakims, has asked the Government of India for the loan of the services of a competent medical officer. The officer selected is Major H. G. Melville, I.M.S., professor of materia medica in Lahore Medical College. Major Melville will probably be leaving for Kabul shortly. Having spent much of his early medical career on the frontier, this officer has a knowledge of both Pushtu and Persian.

Health of Bombay.

The health of Bombay continues to improve and the week ending May 29th shows another decided drop in mortality from plague. Cholera is, however, still present, the deaths for the week numbering eight, three of which, however, were imported cases. These three bring up the number of cases imported from up-country during the season to 174, and it is worth noting that although the complaint has been dragging on all through the season only 45 deaths from cholera besides these have occurred in the city. The figures for the week ending May 29th as regards the general health of the city are particularly interesting, because they show that even including plague Bombay city is in a healthier condition now than it was in pre-plague days. The mortality for the week, including plague, gave a death-rate of 33·18 per 1000; the average rate for this time of year for the five years previous to the plague outbreak was 33·28. Deducting deaths from plague, we find that the remaining death-rate at the present time is only 25·3 per 1000 of the population.

Deaths caused by Wild Animals.

The total number of persons killed in the Punjab by wild animals and snakes during the year 1908 was 953, a very slight increase over the number reported in 1907. Out of this number no less than 925 died from the effects of snake-bite; the number of deaths due to leopards, wolves, hyænas, and other animals (including one death from a species of poisonous lizard) amounting to 28, as compared with 19 last year. The Lahore district kept its position at the head of the list in numbers of deaths from snake-bite. Kangra, as in 1907, was the only district in which persons were killed by wild boars. As regards the number of cattle killed by wild animals, the figures for 1907 were abnormally large. In 1908 the number fell to 1643, being 1188 less than in 1907. The total number of wild animals other than snakes killed in the province in 1908 was 1238, an increase of about 50 per cent. over the figures for 1907. The increase is due entirely to the number of wolves killed (882), which was unusually small in the previous year. 4228 snakes were, it appears, killed in 1908. The number of persons reported to have been killed by wild animals in the United Provinces during 1908 was 194, as compared with 159 in the previous year and 280 in 1906. The increase was largely due to the number of persons killed by leopards in Kumaon, which rose from six to 35, and by wolves in Fyzabad division. There is a man-eating leopard in Almora district on whose head a reward of no less than Rs.500 has been placed. In Bahraich district wolves are said to have taken suddenly to killing people, but as they did not form packs it was not possible to organise measures for extirpating them. The local government suggests that this explanation is not correct, and whether correct or not it is unsatisfactory. The reported mortality from snake-bite decreased from 5080 to 4816 persons. The number of cattle killed by wild animals is reported as 11,083, or nearly double what it was two years ago. This is probably due largely to more careful reporting; it is certain that even now a far larger number of cattle are killed than the figures suggest. Leopards are much the most destructive of wild animals, over 8000 of the cattle being killed by these animals. Kumaon suffers worst in this matter, the Deputy Commissioner of Almora attributing the increased destructiveness of leopards to the wholesale slaughter of game by Gurkhas, who have thus diminished the natural food-supply of the leopards. There was an increase in the number of wild animals reported to have been killed and in the rewards paid for their destruction.

Cholera in Hyderabad.

Cholera has broken out in the dominions of H.H. the Nizam. The part worst affected is Nander and Khandar in the Nander district. Fatal cases are reported in Subzawandi and one in Karwan, both places within the Hyderabad municipal area. The officials of the Nizam's government are dealing with the situation, and precautions are being taken to fight the advance of the disease. In Secunderabad Major F. L. Blenkinsop, I.M.S., in medical charge, and Major Leslie, cantonment magistrate, are prosecuting measures to prevent the introduction of the disease in the cantonment limits. An excellent sanitary system exists in Secunderabad, which is divided into circles, each with its own sanitary staff and appurtenances, but what is a perplexing problem is the tendency of the Kompte class to conceal cases. In view of the severe epidemics in previous years and the wide area over which cholera is now reported to be raging outside, it is most expedient to adopt rigorous precautionary measures for the safety of British subjects and the large garrison adjacent to the town.

June 2nd.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology held on July 1st, 2nd, 5th, and 6th, 99 candidates presented themselves, of whom 50 were approved and 49 were rejected. The following are the names of the successful candidates:—

Basil Fraser Beatson, St. Mary's Hospital; Robert Campbell Begg, M.A., B.Sc. New Zealand, New Zealand and Edinburgh Universities; Percy Lytton Tempest Bennett, London Hospital; James Alfred Ayton Boddy, Manchester University; Arthur Vincent Boyall, [illegible] Hospital; Philip Norman Button, [illegible] ck William Campbell, University [illegible] Weston Clayton, St. Mary's Hospita [illegible] t. Bartholomew's Hospital; Jules M [illegible] Hospital; Rustom Kershasp Dadachanji, L.M. & S. Bombay, Bombay University and London Hospital; Andre Constant Labauve d'Arifat, Guy's Hospital; Arthur Lewis Davies, University College Hospital; David Henry Davies, University College, Cardiff; Satis Chunder De, L.M. & S. Calcutta, L.M. Rotunda, Calcutta Medical College and King's College; Edward Percy Drabble, London Hospital; Christopher [illegible] nster Hospital; Maberly Squire Esler, St. [illegible] ge Frederick Fawn, University College, [illegible] rles Fazan, Middlesex Hospital; Edward [illegible] ab., Liverpool University; Claude Emery [illegible] versity; Charles Alexander Robertson [illegible] Charing Cross Hospital; Harry James Hoby, James Moncrieff Joly, and George Basil Henley Jones, Guy's Hospital; Cornelius Kennedy, [illegible] na, Guy's Hospital; Adolph [illegible] y College Hospital; Walter [illegible] en David Baker Mawson, [illegible] Menagé, Guy's Hospital; Charles Edward Hamilton Milner, King's College; Rustom Dhunjeabhoy Mody, L.M. & S. Bombay, Bombay University and King's College; William Ewart Neale, University College, Bristol; [illegible] y's Hospital; Dyfrig Huws Pennant, [illegible] Herbert Thomas Retallack-Moloney, [illegible] ander Reynolds, St. Mary's Hospital; [illegible] Hugh [illegible] binson, St. Bartholomew's Hospital; [illegible] awala, L.M. & S. Bombay, Bombay U [illegible] Guy's Hospital; Claude William Treherne, St. Thomas's Hospital; Ivan Lindley Waddell, St. Bartholomew's Hospital; and Edward Algernon Weaver, Birmingham University.

At the quarterly examination in Practical Pharmacy held on July 8th and 9th the following gentlemen were approved:—

William Guy Embleton Al [illegible] 's Hospital; Edgar Bernard Argles, St. Mary [illegible] William Atkinson, [illegible] Hospital; Richard [illegible] as's Hospital; Maurice Holdsworth [illegible] ospital; Herbert Rowse Bastard, Guy's [illegible] Hazlerigg Noel Bell, St. Thomas's Hospital; Guy Kenneth Butterworth, St. Mary's Hospital; Rowland Burnell Campion and Kenneth Bleckly Clarke, Guy's Hospital; Richard Christopher Clarke, University College, Bristol; Francis Howard Cleveland, St. Bartholomew's Hospital; Richard William Davies, St. Mary's Hospital; William Alexander Dunn, Otago University and St. Thomas's Hospital; Raymond Gam [illegible] rsities; Frank Garratt, St. [illegible] Greaves, Leeds University [illegible] Cambridge and Leeds Uni [illegible] University; Brabazon James [illegible] and William Henry Harris, St. Bartholomew's Hospital; John Rollo Hayman and William Reginald Huleatt Heddy, Middlesex Hospital; Henry Sydney Colchester Hooper, London Hospital; Job Hughes, Birmingham University; Arthur Ernest Williams Idris, University College Hospital; Gwilym James, B.A. Cantab., Cambridge University and University College Hospital; Ah Chit Jap, Guy's Hospital; Arvor Jones, Liverpool University; Evan Lawrence Jones, Guy's Hospital; Walter Foulkes Jones, B.A. Cantab., Cambridge University and St. George's Hospital; Timothy Joseph Killard-Leavey, Guy's Hospital; Claude King [illegible] Bristol; William Stocks Lacey, L.D.S [illegible] Joseph George L'Etang, St. Bartholom [illegible] McGillivray Loughnane, St. Thomas's [illegible] McIntosh, S [illegible] Reginald Victor Martin, St. Mary's [illegible] asefield, Middlesex Hospital; Char [illegible] 's Hospital; Frederick Meinertzhag [illegible] Hospital; Henry Leslie Messenger, [illegible] lard, Birmingham University; Jo [illegible] Hospital; John Henry Newmarch, B.A. Cantab., Cambridge University and St. George's Hospital; Henry Maurice Dunlop Nicoll, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Meredydd Parry and George Stanley Phillips, University College, Cardiff; Arthur Thomas Pitts, L.D.S. Eng., Middlesex Hospital; [illegible] lliam [illegible] ital; Arthur I [illegible] fred Herbert [illegible] ott Reynold [illegible] Hos- Rhodes, [illegible] dlle pital; [illegible]

Douglas Robertson, St. Mary's Hospital; Hassan Ibrahim Shahin, Cairo and Guy's Hospital; Jack Garland Skeet and Eric John Staddon, St. Thomas's Hospital, Horace Steinbach, [illegible]
Hospital; [illegible]
ell Taylor, [illegible]
aylor, B A. [illegible]
Hospital; [illegible]
t. Andrew [illegible]
iam, Leeds [illegible]
les George [illegible]
Hamersley [illegible]

Royal College of Surgeons of England.—At a meeting of the Council held on July 8th licences to practise Dentistry were granted to the following gentlemen:—

Benjamin Her[illegible] Michigan University, Charing Cr[illegible] Theodore Scott, Middlesex [illegible] and Alexander MacDonald [illegible]

Society of Apothecaries of London.—At the Primary Examination, Part I. and Part II., held recently, the following candidates passed in the subjects indicated:—

Biology.—M. S. Bowen, London Hospital; and J. K. Nariman, Bombay.
Chemistry.—M. S. Bowen, London Hospital; and H. E. Rose, Cambridge.
[illegible]—E. B. Keen, Charing Cross Hospital; [illegible] Hospital, and L. M. Potter, Royal [illegible] ospital
Physiology—J. M. Coplans, Westminster and King's College Hospitals; and W. R. de C. Shearman, Manchester.

Victoria University of Manchester.—The following candidates have been approved for the degree of M.D.:—

G. D. Dawson (awarded gold medal), R. L. Ferguson (commended), C. E. Lea (commended), A. E. Rayner (commended), Elsie M Royle (commended), F. P. H. Birtwhistle, T M. Bride, H. R. Clarke, H. M. Crake, G. F. Porter, and T. W. Walker.

University of Glasgow.—The following have satisfied the examiners in the Fourth (Final) Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.):—

William Shanks Alexander, M A., Andrew Clark Anderson, ‖William Anderson, James Currie Auchencloss, David Barbour, Arthur Munby Bayne, [illegible]
Carl Joseph [illegible]
Munro Camer[illegible]
James Lang [illegible]
M.A., Donal[illegible]
Fletcher, M A. [illegible]
George Glover [illegible]
Charles Gord[illegible]
Adamson Ha[illegible]
Bentley Moor[illegible]
Leishman, Wil[illegible]
B Sc., William [illegible]
M'Intyre, Rob[illegible]
**John Willia[illegible]
M'Whirter, A[illegible]
Hyacinth Ber[illegible]
Findlay Murch[illegible]
[illegible] John Robertson, [illegible] son, Hugh [illegible] Alexander [illegible] nd Steel, [illegible] on Sutherland [illegible] Herrmann [illegible] M'Gruther [illegible]

* [illegible] cal Surgery, (b) [illegible] y. † (a) Surgery [illegible] inical Medicine. [illegible] (a) Practice of [illegible] ry and Clinical [illegible] ** Midwifery.

Trinity College, Dublin.—At examinations held recently the following candidates were successful in the subjects indicated:—

Preliminary Scientific Examination.

Physics and Chemistr[illegible] William H R. M'Carter, Joseph S. English [illegible] Boyers, James A. [illegible] John G. Butt, Ric[illegible] W. D. Magee, Wil[illegible] Mecredy, William [illegible] David H. Hadden, [illegible] Ryan, and Herbert R Ford.
P[illegible] David H. Hadden, [illegible] illiam [illegible] orothy [illegible] or A. [illegible] Small, [illegible] eddy, [illegible] ibald [illegible] R. Toomey, Francis A. L'Estrange, William R. L Waters, George A. Bridge, William D. Pile, Henry J. Brown, Edmund S. Hatte, Charles O'Reilly, George Buchanan, Henry C. D. Miller, Joseph A. Quin, and Etienne J. Malherbe.

Previous Dental Examination.

Physics and Chemistry—George G. Yeates.
Materia Medica—Kenneth C. M'Naught and Henry Kirk.

Intermediate Medical Examination, Part II.

Arthur Chance, Maurice S. Moore, Patrick F. Nunan, William Frier, Hugh E. Williams, Samuel A. Lane, Thomas W. E. Henry, Frederick Burke, and Cecil Rutherford.

Final Medical Examination, Part II.

Midwifery.—Beatrice M. Hamilton, Hilgard Müller, Eric J. Powell, Adams A. M'Connell, Arthur C. Hallowes, Marius A. Diemont, Benjamin A. Molyneux, David Duff, George E. Craig, William H Hart, John W. Flood, and Charles H. Denham.

Foreign University Intelligence.—*Bordeaux:* Dr. Arnozan has been appointed Professor of Clinical Medicine and Dr. Villar Professor of Clinical Surgery.—*Heidelberg:* The Moos Scholarship, the value of which is about £45, has for the first time been carried off by a lady, Frl. Köbeln, for a paper on Otology.

The Hospital for Sick Children, Great Ormond-street.—The fees for attending the Medical School of this hospital have been revised as follows: Special fee for clinical clerks, three months, £3 3*s.*; student's ticket, three months, £5 5*s*; and perpetual ticket, £10 10*s*.

The Children's Sanatorium for the Treatment of Phthisis.—The Children's Sanatorium at Holt, Norfolk, for the treatment of phthisis has just received a gift of £300 "In Memoriam M.T" The amount will be placed to the fund for the permanent building which it is proposed to proceed with when the necessary amount is reached. It is understood some £6000 are required.

Royal College of Surgeons in Ireland.—The following prizes were awarded for the summer session:—Barker anatomical prize (£26 5*s.*): H. R. Tighe; special prize (£21), J. S. Pegum. Carmichael scholarship (£15): J T. Duncan. Gold medal in operative surgery: Miss I. M. Clarke; silver medal, F. N. Harvey. Stoney memorial gold medal in anatomy: J. T. Duncan. Practical histology: S. Griffin, first prize (£2) and medal; I. M. Swanepoel, second prize (£1) and certificate. Practical Chemistry: N. A. Sheridan, first prize (£2) and medal; G. N. Smyth, second prize (£1) and certificate. Public health and forensic medicine: J. T. Duncan, first prize (£2) and medal; K. L. O'Sullivan, second prize (£1) and certificate. Materia medica: J. T. Duncan, first prize (£2) and medal; Vincent J. White, second prize (£1) and certificate. Biology: J. D. Cherry and J. C. Sproule (equal), first prize (£2) and medal each. The lectures and practical courses of the winter session will commence on Oct. 15th.

The Sanitary Regulation of Food Exposed for Sale in London Streets.—The London County Council decided, by 20 votes to 10, at the end of a long sitting on July 13th, to give public notice of its intention to consider the advisability of promoting legislation in the next session of Parliament to secure the observance of proper sanitary regulations in regard to articles of food exposed for sale in the streets. As the public health committee points out in bringing forward the proposal, a large amount of foodstuff is sold in London from barrows and stalls, but although the sanitary authorities have power under Section 8 of the London County Council (General Powers) Act, 1908, to inspect premises such as yards, stables, and arches in which is stored food to be sold by costermongers on barrows, the power of inspection ceases when the foodstuff is placed on the barrows and is taken into the streets. *It is obvious that at this stage* contamination is most likely to occur, and therefore the public health committee proposes that the local authorities shall be empowered to exercise control in the matter. It is further proposed to deal at the same time with the nuisance caused by the accumulation of manure at stables in London. In this connec[illegible]
carried on by [illegible]
horse manure [illegible]
flies, and that [illegible]
regard to the prevalence of flies was manifested in a marked degree at a distance of from 100 to 150 yards and was distinctly appreciable as far away as 200 yards. In addition to requiring the more frequent removal of manure, the public

health committee is of opinion that sanitary authorities should be empowered to deal with the structure and paving of stables, as in the case of cowsheds.

UNIVERSITY OF LONDON.—The following awards have been made at University College, London:—Andrews Scholarships:—For students of one year's standing, £30 each: Classics, Louise W. Stone; Modern Languages, Eileen O'Rourke; Mathematics and Science, R. G. Lunnon. Second Year's Scholarship, £20: D. M'Donald. Carey Foster Research Prize: Caroline Schneider. Oluff Memorial Prize (£15): T. C. Graves. Jews' Commemoration Scholarship, £15 per annum for two years: A. E. Evans. Physics Research Studentships: £60, F. Simeon; £40, B. B. Baker. Science Scholarship awarded by H.M. Commissioners for the Exhibition of 1851: H. E. Watson, B.Sc. Tuffnell Scholarship in Chemistry, £80 per annum for two years: H. J. Page. School Hygiene Certificates: C. V. Aserappa, Mary Babbs, Miss S. E. Fisher, Ethel M. Heaton, Isabella Low, J. H. Paddy, Alice Rhoden, Alice R. Ridgeway, Mrs. Katherine E. Ross, J. H. Willis, and Mrs. Alice van I. Winter.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Pfannenstiel, professor of midwifery and gynæcology in the University of Kiel, at the age of 47 years. He was born and educated in Berlin and was afterwards assistant to Professor Fritsch in Breslau, where he afterwards held several important appointments, the University conferring on him the title of professor. Subsequently he went to Giessen as successor to Professor Löblein, and then to Kiel, where he succeeded Professor Werth. He published a number of papers mostly dealing with uterine tumours, and devised a special incision in certain cases of laparotomy. He was joint author of Winckel's "Manual of Midwifery" and of Beit's "Manual of Gynæcology."—Dr. Friedrich Endemann, Privy Medical Councillor of Hesse. He was very active politically and was for many years a member of the German and Prussian Parliaments. His age was 76 years.—Dr. Henry Cazalis, a well-known French poet, who wrote under the pseudonym of Jean Lahor.

THE MEDICO-LEGAL SOCIETY.—The annual dinner of the Medico-Legal Society was held on July 13th at the Holborn Restaurant, London, with the Hon. Mr. Justice Walton in the chair. Among those present were Sir Cozens Hardy, Master of the Rolls, Mr. H. T. Butlin, Sir William J. Collins, Dr. F. J. Smith, Mr. R. Henslowe Wellington, Dr. G. Pernet, Mr. W. Schröder, honorary treasurer, and Mr. Digby Cotes-Preedy and Dr. William A. Brend, honorary secretaries. A telegram of regret at inability to attend was received from Sir R. Douglas Powell. Sir William Collins, in proposing the toast of "The Law and Medicine," said that probably there never was a time in which the general public was more ready to listen, almost obsequiously, to the last word of medico-legal science, if only it would speak with authority and avoid contradictions. Sir William Collins concluded by pleading for simple language in the proceedings of medical and scientific societies; he especially instanced the Pathological Society, and urged that intellectual jargon should be replaced by the Anglo-Saxon tongue; he deprecated the pathological slang so frequently observed in the proceedings of the scientific societies. This toast was acknowledged by Sir Cozens Hardy, the Master of the Rolls, who observed that the word "evidence" applied to what medical men said in the witness-box was not strictly accurate. In nine cases out of ten medical men were bound to give not evidence but expressions of opinion, and therefore conflicting opinions occurred. Knowledge being what it was, it was impossible for any professional man to state more than his opinion of the cause of any particular bodily condition or of what might be the result of such condition. He objected to the long, unintelligible, and unpronounceable words used by some medical and scientific witnesses, which were the puzzle of juries and the distress of judges. Legislation seemed now more and more closely involving medicine in legal problems, and the appointment of medical referees was a useful reform. Mr. H. T. Butlin, President of the Royal College of Surgeons of England, also replied for this toast, while submitting the toast of "The Medico-Legal Society." Mr. Justice Walton, who responded, said that he was satisfied from his experience that great benefit arose from the association of the lawyer with the medical man in discussing subjects of importance to the welfare of the public. Mr. E. Marshall Hall, K.C., in a witty speech, gave the toast of "Our Guests," which was eloquently acknowledged by Dr. Smith, who, continuing his speech, proposed "The Officers of the Society." After this toast had been duly replied to by Mr. Cotes-Preedy, the proceedings terminated.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Progress of Business.

THE progress made with the Finance Bill in Committee has been slow, the work of examining the proposals relating to land being extremely onerous. Late sittings have been frequent and have put a considerable strain not only on Members but on the staff which is kept in constant attendance whilst the House of Commons is sitting. The proceedings on the Finance Bill and the demands made on the time of the House for passing supply have had the effect of preventing progress being made with several measures, such as the Housing and Town Planning Bill and the Milk Bill. Mr. BURNS has been asked when he intends to proceed with the second reading of the latter measure, but he cannot fix a date. Some regret is expressed that more progress was not made with these Bills earlier in the session.

The West African Medical Staff.

The report of the Departmental Committee on the West African Medical Staff is now available as a Parliamentary paper. Mr. H. J. READ of the Colonial Office was chairman, and amongst the members of the Committee were Dr. T. THOMSON (Local Government Board), Mr. W. H. LANGLEY, C.M.G., F.R.C.S.I. (Principal Medical Officer, Gold Coast), and Dr. J. K. Fowler (late Dean of the Faculty of Medicine, University of London, and senior physician, Middlesex Hospital). The report deals at length with the duties, organisation, emoluments, and selection of officers of the West African Medical Staff.

HOUSE OF COMMONS.

WEDNESDAY, JULY 7TH.

The Mater Infirmorum Hospital, Belfast.

Mr. HUGH BARRIE asked the Chief Secretary to the Lord Lieutenant of Ireland whether it was proposed to affiliate the Mater Infirmorum Hospital (Belfast) to the new Belfast University; and, if so, were its teachers and teaching to be recognised; and would the members of its medical staff be admitted upon the examining board of the University.—Mr. BIRRELL replied: It is not proposed to affiliate the Mater Infirmorum Hospital to the Queen's University. It is proposed by the Medical Faculty that the hospital should be recognised as a place for clinical teaching as it was by the old Queen's College, but this is subject to the approval of the Senate. The appointment of examiners is for the Senate, upon the recommendation of the Academic Council. I have no means of knowing how far the medical staff of this or any other hospital will be recognised by the Senate.

Public Health in Ramsey Urban District.

Mr. BOULTON asked the President of the Local Government Board what steps he had taken to compel the urban district council of Ramsey to make proper provision for the safety of the town against scarlet fever and epidemics arising from the bad water and bad drainage to which his attention was called a year ago.—Mr. BURNS wrote in reply: I have pressed the subject of sewage disposal on the district council. It has directed some temporary measures to be taken, but it urges that the expense of providing a new system of sewers, which would also necessitate a water-supply, would be prohibitive. I have not received any such complaint of default on the part of the district council with respect to sewerage and water-supply as would enable me to take compulsory action under the Public Health Act. No outbreak of infectious disease in the district has been reported to me during the present year.

The Irish Cowsheds and Milkshops Order.

Mr. SHEEHAN asked [illegible] utenant of Ireland, whether any [illegible] appointed as inspectors under [illegible] local sub-sanitary officers who also held the position of relieving officers, as well as other positions under the rural district councils; if so, could he give the names of the district councils, or of any one of them, which had made such appointments; and would he state whether the Local Government Board intended to give its sanction to appointments of this nature, in view of the fact that the time of these gentlemen ought to be already fully occupied if they were efficiently to perform the duties appertaining to other offices held by them.—Mr. BIRRELL furnished the following written reply: I understand that in 68 districts the sanitary sub-officers, who frequently hold the position of relieving officers as well, have been appointed to act as inspectors of dairies. I am forwarding a list of these districts to the honourable Member. The Local Government Board considers it unnecessary to press local authorities to appoint separate inspecting officers of dairy premises in localities where the dairying industry does not assume large proportions. A sanitary sub-officer has opportunity of observing defects or insanitary conditions in dairy premises, and there is no reason to suppose that his time is so fully occupied with other official duties as to prevent his carrying out such inspections. Moreover, under the Board's Sanitary Orders of May, 1900, it already forms part of his duties in a district where no inspector of dairies has been appointed to inspect dairies, cowsheds, and milkshops, and to report to the sanitary authority thereon. The sanction of the Board is only required so far as concerns the remuneration of officers under the Dairies Order.

THURSDAY, JULY 8TH.

Dublin Hospitals and the Royal Irish Constabulary.

Mr. HAZLETON asked the Chief Secretary to the Lord Lieutenant of Ireland on what grounds Steevens's Hospital was selected by the Royal Irish Constabulary for the treatment of constables; whether the hospital enjoyed a monopoly among Dublin hospitals for Royal Irish Constabulary patients; and what sums per week were deducted from

patients. Single men pay 2*s.* 3*d.*, married men 1*s.* 4*d.*, and recruits 1*s.* 10*d.* per day for treatment in the hospital.

Public Experiment on a Bulldog.[1]

Mr. ELLIS GRIFFITH asked the Secretary of State for the Home Department whether his attention had been called to a public experi

had been registered by the licensee for this purpose under section 7 of the Cruelty to Animals Act, 1876; and whether any action had been, or was being, taken in reference to the matter.—Mr. GLAD-

stances?

Insanitary Houses in Donaghadee.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the report of the

The Sale of Margarine in Ireland.

Mr. DEVLIN asked the Vice-President of the Department of Agriculture (Ireland) whether he was now in a position to state
what means the De protect the public,
and especially the from being sold
margarine instead of plied (by written
answer): The duty and Drugs Acts
primarily devolves o epartment can, in
certain circumstances, have samples of articles of food taken for

MONDAY, JULY 12TH.

Public Health in Ramsey.

In reply to Mr. BOULTON, the President of the Local Government Board said that he was

pulsory action under the
that one of the medical
should visit the district an

Typhoid-Carriers at Millbank.

TUESDAY, JULY 13TH.

The Spirit Tax and Drugs.

Sir THOMAS BRAMSDON asked the Chancellor of the Exchequer whether he could state what would approximately be the loss on the spirit tax if a return were allowed of the additional duty on spirits

relied upon to make an accurate return of the spirits so used.—Mr. HOBHOUSE (on behalf of Mr. LLOYD GEORGE) replied: My right honourable friend has no data which would enable him to give the information required by my honourable friend. Except in the case of drugs prepared on the premises he does not see how officers of the institutions in question would be able to make an accurate return of the amount or strength of the spirits used.

The Indian Medical Service and Professional Fees.

The Board of Trade and Colour Tests.

Mr. HENNIKER HEATON asked the President of the Board of Trade whether there was any civilised country in the world, besides our own, which regarded the wool test, the official test of the Board of Trade, as a reliable test for colour blindness, whether he was aware that not a
country was of opinion
ther he could state how
of Trade, either those
had any knowledge of
(by written answer)
countries which have
colour blindness in the
the Board of Trade on
the advice of a committee of the Royal Society, which comprised both eminent physiologists and physicists, and I have reason to think that the highest scientific opinion is in favour of its efficiency. One of its advantages is that it can be applied by persons who possess no knowledge of physiology or ophthalmology. No such knowledge is therefore demanded of the Board of Trade examiners in the first instance. But in the supervision of their tests, in the instructions of their examiners, and in conduct of their special examination on appeal, the Board have the advantage of the services of two acknowledged authorities on colour vision, both Fellows of the Royal Society, who hold the degree of Doctor of Science.

WEDNESDAY, JULY 14TH.

Women and the Diplomas of the Royal College of Surgeons.

Mr. V. H. RUTHERFORD asked the Secretary of State for the Home Department whether, in view of the fact that the Royal College of Surgeons was unable, through the provisions of the Medical Act of

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bartlett, Jacob Harry, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Tintern District by the Chepstow (Mon.) Board of Guardians.

Clarke, N. D., has been appointed Dental House Surgeon at Guy's Hospital.

Dobson, J. R., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Royal Hamadryad Seamen's Hospital, Cardiff.

Edwards, J. C., L.R.C.P. & S. Edin., has been appointed District Medical Officer by the Merthyr Tydvil (Glamorganshire) Board of Guardians.

Emerson, Herbert Bree, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer of Pershore (Worcestershire).

Garrett, R. R., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bishopstoke District of the county of Hants.

Lithgow, J., M.D., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Cleland District of the county of Lanark.

Mulcahy, P., L.R.C.S. Irel., L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ballinamore District of the county of Leitrim.

Pim, Arthur Augustus, F.R.C.S. Edin, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer by the Beaminster (Dorset) Board of Guardians.

Ryce, R. S., M.D. Irel., has been appointed District Medical Officer by the Merthyr Tydvil (Glamorganshire) Board of Guardians.

Smyth, Thomas Edward, M.D., B.Ch. Dub., has been appointed Medical Officer to Kelly College, Tavistock (Devon).

Spain, H. G., has been appointed Dental House Surgeon at Guy's Hospital.

Stuart, J. H. W., has been appointed Dental House Surgeon at Guy's Hospital.

Warner, H. F., M.B., B.S. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Fakenham District of the county of Norfolk.

White, J., M.R.C.P. Irel., M.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Tullaroan District of the county of Kilkenny.

Williams, L. A., M.D. Edin., D.P.H. Liverp., has been appointed Medical Superintendent to the Bradford Educational Authority.

Young, Ernest, M.D. Durh., has been appointed Clinical Assistant to the Out-patient Department of the Mount Vernon Hospital for Consumption and Diseases of the Chest.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Belgrave Hospital for Children, Clapham-road, S.W.—House Surgeon for six months. Salary at rate of £20 per annum, with board and residence.

Birmingham Infirmary.—Assistant Resident Medical Officer; also Assistant Resident Surgical Officer. Salary in each case £104 per annum, with apartments, rations, and attendance.

Birmingham, Queen's Hospital.—House Surgeon for five months. Salary at rate of £50 per annum, with board, lodging, and washing.

Birmingham, University of.—Walter Myers Travelling Studentship. Value £150.

Blackburn and East Lancashire Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, washing, &c.

Bridgwater Hospital.—House Surgeon, unmarried. Salary at rate of £80 per annum, with board, lodging, and washing.

Bristol Royal Infirmary.—Honorary Surgeon.

Burnley, Victoria Hospital.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing.

Cambridge, Addenbrooke's Hospital.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

Cameron Hospital, West Hartlepool.—House Surgeon, unmarried. Salary £100 per annum, with board, rooms, and laundry.

Cancer Hospital, Fulham-road, London, S.W.—Surgeon.

Canterbury, Kent and Canterbury Hospital.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board and lodging.

Cardiff Infirmary.—House Surgeon for six months. Salary £53, with board, residence, and laundry.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—Assistant Surgeon.

Cheltenham General Hospital.—Surgeon-in-Charge of the Branch Dispensary, unmarried. Salary £80 per annum, with board and lodging. House Physician, unmarried. Salary £70 per annum, with board and lodging.

Chester General Infirmary.—House Physician. Salary £90 per annum, with residence and maintenance.

Chesterfield and North Derbyshire Hospital.—Junior House Surgeon. Salary £80 per annum, with board, apartments, and laundry.

Derbyshire County Council.—Assistant Bacteriologist. Salary £150 per annum.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £55 per annum, with board and lodging.

Exeter, Royal Devon and Exeter Hospital.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

Glasgow District Mental Hospital, Lenzie.—Junior Assistant Medical Officer. Salary £125 per annum, with board, lodging, &c.

Govan Parish School Board.—Principal Medical Officer. Salary £500 per annum.

Hackney Union Workhouse, Homerton.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with rations, apartments, washing, and attendance.

DEATHS.

ORME.—On July 11th, at the Red House, Matlock, Albert L'Estrange Orme, L.R.C.P., L.R.C.S.I., aged 45 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE RISK OF INCURRING DIGITAL CHANCRE IN MIDWIFERY PRACTICE.

To the Editor of THE LANCET.

SIR,—It has always surprised me that medical men in general have so little to say about the digital chancre. Every man engaged in practice amongst the poorer classes, and especially near any of our seaports, must have been struck with surprise at the large number of cases of grave venereal disease which he is called upon to treat. These men live their ordinary social life in spite of warnings, which, of course, any medical man who saw them professionally would feel bound to give. The inevitable consequence is that persons engaged in midwifery practice in the district will be confronted with many cases of ulcers of undoubted specific origin. If the medical attendant makes his first vaginal examination of such patients with the bare forefinger he runs a certain risk of infection, which is a vastly increased risk if there be any abrasion on the finger.

No doubt many readers will consider that I am going over very old ground in giving this warning, and my only defence is that I have seen one case of digital chancre in a medical man and have heard well-authenticated reports of two others brought about in this way. When we consider that it is very easy to attend a confinement all through and have no suspicion whatever of the presence of venereal disease, and to have the child brought to us in three months' time suffering from "snuffles" and condylomata ani, it is obvious that this [illegible] medical men to wear them as a routine thing at all confinements. They are better for the patient, as they can be rendered far more sterile than the naked hand, and I have tried to show that they are infinitely better for the medical practitioner also.

I am, Sir, yours faithfully,
ALBERT SHEPPERD, L.S.A. Lond., &c.

Brixton, S.W., July 10th, 1909.

WORKHOUSE AND SPA.

A MEDICAL correspondent [illegible] a newspaper report of [illegible] at which a letter was [illegible] their control. This poor fellow was a chronic invalid who had evolved the following plea for a proper course of spa treatment at the expense of the ratepayers:—

> Dear Board of Guardians,—I hope ye will send me to Bundoran for a few months to get cured ...... I am badly with the spine of my back down in my knees, and the stiffness of my joints where the spine of my back ought to be. ...... And ye had great pity for me when ye were up, so I hope ye will send me to Bundoran to the best [illegible] poor disabled unfortunate creature. I have a pair of trousers but no coat and I would like to be decent going to the hotel where ye will send me to in Bundoran, so I hope ye will treat me decent and give me a good suit of clothes going away with me. Dont mind sending nurses with me to Bundoran. They are too expensive and I dont want such a burden on the Union, although the nurses are wanting me to intercede with ye, and bring them with me to Bundoran, but I will get a man friend of my own to come. Please send me soon. Good-bye and thanks,
>
> B. K.

The board of guardians were so unsympathetic as to conceive they had finished their duty in the matter by entering this novel request as "Read" without further comment. *There is more in B. K.'s suggestion that one big expense is less burden to the rates than* [illegible] o for [illegible] the [illegible]

SOME LESS USED MEDICINAL BARKS.

A COMPARISON of the drugs in use in different countries frequently calls attention to the somewhat restricted distribution of some of them. In the United States, for example, a preparation very generally prescribed for coughs is a compound syrup of white pine, which contains white pine bark combined with various other drugs, including wild cherry bark, blood root, spikenard, balm of Gilead buds, and sassafras, with morphine acetate and chloroform. Many other preparations that are much used in the United States contain vegetable drugs as unfamiliar to British prescribers as are some of those mentioned above, and on this account it is of interest to call attention to a monograph on "American Medicinal Barks," recently written by Miss Alice Henkel.* *35 different barks are described* and illustrated, the intention of the compiler being to provide accurate descriptions of these drugs as a guide to growers, collectors, and druggists. Reference may here be made to the brief notes on the therapeutic action of some of the barks mentioned. White pine bark (Pinus strobus) is used as an expectorant; its taste is mucilaginous, bitter-sweet, and astringent. Butternut bark (Juglans cinerea) has a faint odour and an acrid, bitter taste; it is a mild cathartic and tonic. Prickly ash bark (Xanthoxylum americanum and other species) has a very pungent and somewhat bitter taste. It is employed medicinally on account of its alterative, stimulant, and sialagogue properties and in rheumatism is credited with increasing the volume of the secretions. It is used externally as a counter-irritant. The bark of the root of the cotton plant (Gossypium hirsutum or herbaceum) appears to have emmenagogue properties. In the hands of the physician it may be a valuable remedy, but it is largely employed among the coloured people for illegitimate purposes. The bark is free from odour, but it has a faintly acrid and astringent taste. Dogwood bark (Cornus florida) is used in medicine for its astringent, tonic, stimulant, and febrifuge properties, and in the fresh state it is said to be emetic. The bark of the root was official in the United States Pharmacopœia from 1830 to 1890. During the Revolutionary war it was much employed as a substitute for cinchona bark. It has an astringent, bitter taste, but practically no odour. Fringe-tree bark (Chionanthus virginica) possesses tonic, febrifuge, and laxative properties, and is also said to have a narcotic action. Cramp bark (Viburnum opulus), as the name indicates, is used as an antispasmodic, and it is also said to possess tonic and astringent properties. It is practically odourless and the taste is astringent and bitter. Black haw bark (Viburnum prunifolium) is credited with similar properties, and is a more familiar remedy to us. Both cramp bark and black haw are largely prescribed in the form of a compound elixir in the treatment of dysmenorrhœa and other uterine ailments where a uterine tonic and sedative remedy is required. Of the barks that are employed to a less extent the following are described in the Bulletin: Aspen (Populus tremuloides), a tonic employed in the treatment of intermittent fever; bayberry (Myrica cerifera), tonic and astringent; ironwood (Ostrya virginiana), tonic, alterative, and antiperiodic; white oak (Quercus alba), a powerful astringent, also an antiseptic; magnolia (Magnolia acuminata and other species), tonic and sudorific, used in pyrexial states; tulip poplar (Liriodendron tulipifera), a bitter, stimulant tonic, useful in fevers, rheumatism, and digestive disorders; spicebush (Benzoin benzoin), a vermifuge and also given in fever; wafer ash (Ptelea trifoliata), possessing tonic properties and used in fevers and as an anthelmintic; moosewood (Dirca palustris), a decoction of which is used for its emetic, laxative, sudorific, and expectorant properties; and buttonbush (Cephalanthus occidentalis), a febrifuge, expectorant, and diuretic.

* Bulletin No. 139, Bureau of Plant Industry, U.S. Department of Agriculture, Washington, D.C., 1909, pp. 59.

THE DANGERS OF VERONAL.

ON July 9th, at the Kensington coroner's court, Mr. C. Drew held an inquest upon an artist who had been found drowned in his bath. It was given in evidence that the deceased had been in the habit of taking large doses of veronal to induce sleep and that on two occasions he had been found insensible from the effects of the drug. He had been attended by Dr. G. J. Bagram, who gave medical evidence to the effect that he was satisfied the fatality was due to the same cause, although the post-mortem findings indicated asphyxia from drowning. In his opinion the deceased, whom he did not see after the accident until life had been extinct for some hours, had taken veronal which did not produce an immediate effect, but the hot water of the bath had accelerated the action of the drug, causing sudden drowsiness which led to the death by drowning. The explanation certainly seems a reasonable one, for we can hardly conceive of any person drowning himself either by accident or intention in a bath whilst in a condition of consciousness. An open verdict was returned, and the case serves to direct attention once more to the dangers of a drug habit that has now been responsible for several fatal accidents.

NATIONAL FOOD REFORM ASSOCIATION.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to inform your readers that the National Food Reform Association has now opened offices at 178, St. Stephen's House, Westminster, S.W., overlooking the Houses of Parliament. May I also mention that we have just published a penny booklet entitled "Economical Dishes for Workers," which will be found useful by district visitors, temperance and other social workers. It contains a number of simple recipes which have been tested and have proved both popular and economical. A specimen copy, with full particulars regarding the association, may be obtained by sending a stamped, addressed envelope to the secretary at the above address.

I am, Sir, yours faithfully,
NEVILLE S. LYTTON, Chairman.
178, St. Stephen's House, Victoria Embankment, Westminster
Bridge, London, S.W., July 9th, 1909.

THE COMPOSITION OF ARGEMONE MEXICANA.

SINCE the year 1841 there has been considerable discussion as to whether *Argemone mexicana* contains morphine. This drug has been used to some extent in the treatment of morphinism, and reference was made to its use in THE LANCET of March 2nd, 1907, p. 629. From the experiments of M. W. Dulière, described in the *Bulletin des Sciences Pharmacologique* for May, it now seems clear that the drug does not contain morphine. Samples of the dried and fresh plants were carefully analysed, and it was found that the alkaloids present consisted of protopine and berberine, the reactions for morphine giving negative results. It is satisfactory to know more definitely the composition of this drug as its therapeutic work may now be assessed at its true value. It is of interest to note that a proprietary article named "Antimorphine," which has been vaunted for the treatment of the opium habit, was found by M. Dulière to contain morphine. As this remedy is said to be prepared from *Argemone mexicana* M. Dulière draws the conclusion that the morphine in "Antimorphine" must have been added intentionally.

FRENCH DICTIONARIES.

To the Editor of THE LANCET.

SIR,—In reply to "Guillaume," who asks for a small French dictionary (in French) in THE LANCET of June 26th, the smallest I know is Bescherelle, 13cm. × 9cm. × 2cm., half bound.

I am, Sir, yours faithfully,
Geneva, July 7th, 1909. (DR.) A. CORDES.

To the Editor of THE LANCET.

SIR,—I note an inquiry for a satisfactory French dictionary in THE LANCET of June 26th, on p. 1877, and believe that "Guillaume" will find Bellows's Dictionary for the pocket to be the best, although it contains French and English. I have found all the words explained which "Guillaume" mentioned and might cite one. "Conduire *v.a.* (*Table* 51—for full conjugation of this irregular verb) to conduct [emmener) to take: to lead: to guide [accompagner) to take [diriger) to direct [voiture) to drive [nav.) to steer [marchandises) to carry [affaires) to manage: to carry on [fluides) to convey [fig.) to conduce. Se—,To find one's way: to be conducted: to behave (one's self) to go on." While, on the same page, underneath I find: "Conduct *v.a.*, conduire (to, à] introduire (into, dans] diriger [des opérations, etc.] —one's self, se conduire: se comporter."

I have used this little book for more than 30 years and seldom found it fail. Of course, *Littré* is indispensable for a full knowledge of details; for example, two columns are required for this one word and the synonyms given are *mener* and *guider*.

One hopes that another Bellows will arise to serve us equally well in German and Italian.

Yours truly,
Perth, July 10th, 1909. A. R. URQUHART.

*** We can endorse our correspondent's opinion of Bellows's Dictionary, which contains an extraordinary amount of information in a small bulk, but we would point out that "Guillaume" inquired for an all French dictionary.—ED. L.

"WHERE IS IT?"

RECENTLY a rare and curious little booklet for the waistcoat pocket, entitled "Where is it? a Handbook to the Urinals, &c., of London," and published at 6*d.* in 1852, changed hands at £4 5*s.* In 1851, the year of the Great Exhibition in Hyde Park, it was found difficult in the absence of public urinals to promote public decency, so this little booklet was issued as "a friend in need," indicating where the nearest urinals were to be found in London. The streets where the urinals were situated are mentioned in alphabetical order. Even so late as the early "eighties" some such guide would often have been of service, for it must be remembered that the princely urinals at the disposal to-day of the Londoner are a feature of modern London.

◆

Red Dwarf is advised to call on the two practitioners, whose seniority and position make them prominent in medical circles, and ask their opinion. His course is dependent upon local views.

P. L. G.—The only general advice we can offer is that such certificates should not be given.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1909, which was completed with the issue of June 26th, and the Title-page to the volume, were given in THE LANCET of July 3rd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	
One Year	£1 12 6
Six Months	0 16 3
Three Months	0 8 2

Subscriptions (which may commence at any time) are payable in advance. *Cheques and Post Office Orders (crossed* "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

A Lecture

ON

THE DESIRABILITY OF EARLY OPERATION IN ACUTE CASES OF APPENDICITIS,

TOGETHER WITH AN ANALYSIS OF 190 SUCH CASES OPERATED ON AT ST. GEORGE'S HOSPITAL.

Delivered at St. George's Hospital on June 29th, 1909,

BY G. R. TURNER, F.R.C.S. ENG.,

SURGEON TO, AND JOINT LECTURER ON SURGERY AT, ST. GEORGE'S HOSPITAL.

GENTLEMEN,—I wish to bring before you this afternoon my experience of operation on appendicitis during the acute stages. The question of its necessity may be rather hackneyed, but though much has been written and said about it, it is very far from being settled, and many valuable lives are lost because it is *not* settled, because there is a false and unjustifiable timidity in facing the necessary. We no longer hesitate as surgeons of 50 years ago did about operating at once on a strangulated or obstructed hernia. I submit that appendicitis, which may be nearly as dangerous, in the years to come should follow the good example of hernia and very rarely escape its antidote—early operation. Four years ago, in 1905, at a discussion before the Royal Medical and Chirurgical Society, initiated by Sir Frederick Treves, the experience of various large hospitals on acute and chronic cases of appendicitis was brought forward. On analysing these at the time of the discussion in 1905 I found the number of cases operated on between attacks in five large London hospitals was 1209; seven of these died, making a mortality of ½ per cent. Other cases, more acute, and operated on during the attack, were 1568, of whom 376 died, an average mortality of 23·9 per cent. Of 795 cases (not classified) operated on at another large hospital 136 died. The total number of cases altogether brought forward was 3572, and of these 519 died, an average mortality of 14·2 per cent. In a summary by Mr. Stephen Paget and Mr. Stanley Boyd published later it appears that there was in 1361 cases operated on *during a period of quiescence* a mortality of 1·1 per cent.; *abscess without general peritonitis*, 863 cases, 83 deaths, mortality 9·62 per cent.; *operations when general peritonitis was present*, 242 cases, with 177 deaths, mortality 73 per cent. Such, then, was the experience of London surgery up to 1905, but we must remember that these statistics included a large number, if not all, of the early operations when operators were less experienced than they now are, when cases were left longer, and the methods employed not nearly so safe or so satisfactory. For instance, in our own Hospital here, St. George's, between the years 1892 and 1898 no less than 28 per cent. of the acute cases died after operation; between the years 1900 and 1905 only 15 per cent. We must remember, too, that more than half of the cases between the years 1892 and 1898 were admitted primarily into our medical wards and came, with the views of treatment then prevailing, under the surgeon's care later perhaps than they do now when it is the rule rather than the exception for them to go straight to a surgical ward.

Looking at these statistics, which give a mortality of only ½ per cent. or 1 per cent. for cases operated on between attacks, as against the terrible mortality of nearly 24 per cent. of those operated on during attack, it would seem at first sight that they suggest that operation during attack should not be undertaken; but I would ask you to remember that this great mortality of cases operated on during an attack was due to the fact that they had been left until *late*, and certainly in many cases until *too late* for satisfactory surgical interference; and in bringing before you this afternoon my own statistics of my operations on acute cases I am going to give you the experience of a surgeon who operates as early as he can, but not by any means as early as he would like. It is not the operation which is, or should be, the dangerous thing, it is the condition too often found at the time of that operation. Some surgeons go so far in their advocacy of early operation as to say that in a case seen *ab initio* by a medical man no abscess should ever be allowed to develop, and certainly if all cases, when a reasonably sure diagnosis has been made, were at once operated on abscess could not so often supervene, nor would other complications be found that have led in the past to the high mortality that was disclosed in 1905.

How often has waiting for a brief while seemed successful! The initial fever passes, the tenderness and abdominal rigidity perhaps subside, or nearly so. The bowels, duly castor oiled, act, and both patient and medical man hope and think the worst is over—for a day perhaps pulse and temperature are down to normal, and then possibly on the much-talked-of fifth or sixth day, or later, up the temperature runs, the pulse is once more rapid, the aspect of the patient changes, anxiety is on his flushed countenance, his tongue is furred and brown, his lips dry and cracked, his eye bright with fever, [illegible] be felt in hi [illegible] abscess or [illegible] ditions may be accompanied by but few general symptoms, but should always be suspected after an appropriate lapse of time. That general quietude may be associated with grave local symptoms is yet another argument for early operation.

Turning to my own acute cases, all of them hospital ones, for I prefer in the matter of statistics not to include private cases which cannot be verified, during the years 1894 to 1905 at this hospital I operated on 101 acute cases during the attacks: 57 of these had abscess, 6 of them died, 44 had no abscess, 4 of these died, making altogether a percentage mortality of under 10. During the years 1905 to 1909, tables of which cases by the kindness of Mr. G. D. H. Carpenter I have here, I operated on 89 acute cases during attacks: of these 36 had abscess and 3 of these died, and of the other 53 with no abscess 2 died, making an average mortality of under 6 per cent. Putting the whole of these *acute* hospital cases together, from 1894 to 1909 there are 190 cases with 15 deaths and an average mortality of 7·8 per cent. Were my acute private cases added this mortality would be reduced to about 6·5 per cent. Analysing these 15 deaths in the 190 hospital cases, in all the appendix was gangrenous, in nine cases abscess was present: one patient died on the table from chloroform, two were admitted almost moribund, one was complicated by abortion at the *six month, seven had general peritonitis* at the *time* of operation, and in two the sloughing had extended from the appendix to the neighbouring cæcum. I think I may say, therefore, that none of these fatal cases would have recovered without operation, and were I to exclude, as I reasonably might, the death from chloroform and those who were already all but moribund from peritonitis, the mortality of the hospital cases of 7·8 would be reduced to 6·3 per cent. I have had 39 cases running with only one death, and my last 42 cases without any, although many of these were gravely ill with sloughing of the appendix and abscess consequent thereon. I have never refused to operate on any case, however bad. These are not statistics of selected cases, but show the mortality of acute (often late) cases operated on during attacks, not the mortality of all cases, including those operated on between attacks; the consideration of the latter I am purposely excluding this afternoon.

Some years ago, and indeed now with many medical men, a policy of waiting was, and is, advocated—waiting till the clouds roll by; but sometimes they never do do this, and then the unfortunate patient is operated on under disadvantageous circumstances at a late period, when abscess, perforation, or mortification may be present; for not only has he waited, but usually his damaged intestine has spent the waiting time in resisting colon-disturbing enemata and the attacks of calomel and other noxious drugs. There was a time when, realising that abscess might be forming, some people advocated, and for all I know may still advocate, deliberate waiting until that abscess formed and the pus localised. With this treatment of so dangerous and uncertain a condition I cannot in the least agree. The causes of delay are many; too often the patient or his friends are responsible; sometimes an excess of examination by the latest scientific methods is only waste of valuable time; sometimes the doctors have "Let I dare not wait upon I would." Here is a typical case—alas! also a true one (not in my own practice).

A young woman experienced sudden pain on a Monday evening in the right side of the abdomen and was seen by a medical man the next morning. The pain increased during the day and was very severe at night; abdominal distension came on, the temperature rose to 101° F, and the pulse was rapid; fomentations were applied and morphia was given. The blood was examined; there was no leucocytosis. By Wednesday the pain was severe and constant diarrhœa set in. There were great restlessness, constant pain, and increasing distension; a flatus tube was passed; more morphia was given. On the Thursday the pulse went up to over 150, the patient's colour and appearance became very bad, and an operation was performed late in the day. There were a large burst abscess and general peritonitis. In spite of transfusion and saline injections the collapsed patient died a few hours afterwards. Do not such cases cry aloud for *early* operation? Can they by any possibility be seriously taken as arguments against operating during an attack? Yet these cases or similar ones go to swell the statistics of mortality of "during attack" operations. What we want is the result of *early* as opposed to *late* operation and waiting, not the result of operations on "too late" cases. Do not be put off by the fatal quiet induced by morphia, by blood counts, or by diarrhœa; it is better to be "bloody, bold, and resolute"—to use your clinical instinct and not be afraid to do an early, and if early a safe and easy, operation.

In my list of cases you will not have seen, nor have I used the word "fulminating," although I know that some cases are as bolts from the blue, very rapid in their disaster and fatal, yet I think that these fulminating cases are fewer than is generally thought to be the case, and I cannot help suspecting that sometimes, not having perhaps properly realised the gravity of early symptoms, we may have got under the umbrella of fulmination to excuse the length of the latent period of our diagnosis. Burst abscesses and perforations of an already inflamed appendix may give rise to all the symptoms of fulmination. Let us consider for a while the arguments for and against early operation, and remember that I do not advocate it unless it is certain that there is something gravely wrong in the abdominal cavity. Appendicitis in all its stages comes under this definition. First of all it is argued, and reasonably, that one cannot be sure that appendicitis is present, especially perhaps in women, where the ovaries or uterine appendages on the right side may be the cause of the trouble. Rectal or vaginal examination is here specially indicated, though often exploratory operation alone can clear up the mystery. Like other surgeons, I have met with cases sent up for operation as appendicitis which simulated it, but were not appendicitis. Let me briefly relate to you one or two of these.

The first case was a woman, who two years previously had been in a large London hospital suffering from what was called appendicitis. When she came to St. George's Hospital there was marked tenderness in the iliac fossa; she was sick and faint and had shivering, her attack commencing by pain low down in the right abdomen. On opening the latter through the right rectus muscle no trace of large intestine was to be found. There was acute volvulus of the small intestine in the right hypochondriac region. Considerable difficulty was experienced in finding the cæcum; both it and the appendix, which was large, were found healthy but abnormally placed in the left hypochondrium, and the large intestine was obviously very much less in extent and smaller than usual; the other viscera were normal. She made an uninterrupted recovery. In this case, then, there was that fœtal condition of the intestine met with in an early stage of our development. Her symptoms pointed, with the history, to appendicitis rather than to acute intestinal obstruction. Early operation in her case was of the utmost possible benefit.

Another case, again sent up as appendicitis, with sudden severe abdominal pain, marked shivering, rapid pulse, tenderness chiefly in the right iliac fossa and vomiting, proved to be a retro-peritoneal hernia; about 2 feet of collapsed small gut were dragged out apparently from the fossa duodeno-jejunalis. There were old peritoneal adhesions around and a stercolith in the appendix which was removed. The boy made an uninterrupted recovery.

Yet another case: a woman seized with severe abdominal pain, at first general, quickly shifting to the right iliac fossa. There was nausea but no vomiting; there was a history of cellulitis and peritonitis two years previously. The pulse was 120 and the temperature was 101° F. She was drowsy from opium that had been given to her before admission. The abdomen was distended, and there was tenderness which wa most marked in the right iliac fossa. This case on operati proved to be a ruptured ovarian cyst: originally springing the left side, it had ruptured on the right. The cyst w deeply situated and adhered to adjacent bowel. The rig Fallopian tube was dilated with fluid and the right ovary w cystic; both were removed, as was also the ovarian cys The patient made a good recovery.

These three cases, then, simulating appendicitis, we operated on early and successfully. A policy of waitin might have been fatal in all.

It has not as yet been my lot to cut down on what has bee diagnosed as appendicitis and to find nothing. I have, hov ever, found both perforated gastric and perforated duoden ulcer. Early operation in each case saved the patient's lif So much for pardonable mistakes in diagnosis. If you kee to the rule of operating when you are sure there is somethin gravely wrong inside the abdomen, I do not think you your patient will come to much harm. I am ready to allo that certain diagnosis is not always possible, but I contend that nowadays the experience that we all have ha makes the diagnosis of appendicitis not so difficult or doubtful as it once was.

Let us consider for a moment what happens if a case appendicitis is left without operation. Recovery, tempora or permanent, may ensue, but the temporary recoveries mal a large percentage. Mr. H. S. Pendlebury, some years ag writing to me as to the cases in this hospital between the yea 1892 and 1898, says of them: "An interesting fact is th one attack predisposes to subsequent attacks in about 30 p cent. of all cases." With reference to permanent recoverie some that are thought to be permanent are not so. remember the case of a friend of mine who had a very b attack of appendicitis in the days when operation was co sidered as a last resource. He was not operated upon. Som what to the surprise of those who were looking after him, recovered, and he lived for some 15 years or more, nev quite well, haunting places like Carlsbad, Harrogate, ar other health resorts, but apparently with no second attack his trouble. After being obscurely ill with abdominal sy ptoms for some two or three weeks he died comparative suddenly. No operation was done, no post-mortem exan nation was made, but I cannot help thinking that his dea was connected with his old enemy—appendicitis. If recove does not take place, the case, if left, will go on abscess, to gangrene, or to perforation. Natural recover after abscesses bursting into the intestine or through Dougla pouch are on record, but are rare. One of the latter I h had recently in my own practice, but I take it that no would argue that if abscess is present operation should not performed. The same also with gangrene and with perfo tion. Looking at the cases of what I have called tempora recovery, surely the wise man who has "temporaril recovered will have his appendix removed. When I s this, I am aware that some eminent surgeons would prefer see the appendix transplanted to the front of the abdomin wall, allowing it, if necessary, to be used as a means treatment of the colon, and that a distinguished scient regards the organ as likely to delay the onset of old age. F myself, I would chance the latter and would agree with t remark of an eminent physician that he would sooner ha his diseased appendix in his pocket than stitched to groin. It is, in my opinion, when colitis only is present th appendicostomy rather than appendicectomy is indicated.

Amongst the arguments against operation is the inju done to the abdominal wall, but let me here remark that done early no drainage-tube or gauze is required, and th the gridiron incision, by which the abdominal muscles a separated rather than divided, and the incision through t sheath of the right rectus muscle leave the abdominal wal practically uninjured and sound. The person who waits ar operates late has to think of the abdominal wall; not so who operates early. Early operation is easy and, I conten safe—safe, I mean, in the hands of a surgeon accustomed abdominal work and prepared to deal with complications other unexpected conditions that he may meet with. I not advocate early operation by the inexperienced operat in out of the way country places, where perhaps prop assistance at the operation and in giving the anæsthetic not at hand. Such cases must be left to wait until adequa arrangements for operating can be made. The abdomin wall then should only be weakened, and then not alway when gauze packing and tube drainage are required. If there be a subsequent small ventral hernia it is, as a rule, the result of *late* operation. It is not irremediable, and after all but a small price to pay for one's life.

The danger of peritonitis following operation has been advanced as an argument against it, but surely the danger of peritonitis is much greater in all cases if the patient is left. So much for some of the arguments against early operation. The arguments for it are that in itself it is not dangerous; that when done early the abdominal wall is not damaged; that recovery after it is rapid, there is no prolonged convalescence with tubes and gauze packing; that the appendix is dealt with before abscess and other septic complications have time to develop; that such risks as pelvic, post colic, subphrenic, or even secondary liver abscess are avoided; that any peritonitis present is not, as a rule, of that general septic variety seen in the later stages; that the patient has one illness, and gets rid once for all of a constant source of danger—a matter of moment to working men and to those whose lives may have to be lived in outlying parts of the Empire or in any Ultima Thule of our own country; that many grave conditions of the appendix and its vicinity are not always accompanied by the danger-signals of rigor, high fever, rapid pulse, rigid abdomen, vomiting, &c., and so there is developed a false and fatal sense of security if a waiting policy is practised.

I have not time to say much about the details of operation in these bad late cases when abscess or gangrene of the appendix is present, except to impress on you the necessity of packing the neighbourhood with either gauze or sponges, while the contaminated parts are being dealt with, and to open any abscess that may be present with the utmost possible care. No pulling or slicing can be allowed here. Personally, as far as possible I relieve the tension of the abscess gradually by a small opening and mop up the foul matter as it exudes by stick sponges, and although it is now the fashion of most surgeons to discard the use of the marine sponge, I cannot help thinking it has much more capillary attraction and sucks up foul discharges and blood much better than the ordinary swab; in fact, I agree with Sir W. Watson Cheyne and the late Mr. Greig Smith in infinitely preferring a sponge to a swab. In my private cases I never use a sponge twice; at the hospital here only those that have been used for clean cases are sterilised and used again. Adequate tube-drainage and proper packing with gauze are most important when the septic or abscess area is deeply situated. I make no counter-openings, never irrigate or wash out the peritoneal cavity, and regard the gauze as packing only. Secondary abscesses and second operations are usually due either to lack of proper precautionary drainage or the premature removal of the gauze packing. I prefer, in spite of the greater pain and inconvenience, to have this done gradually day by day than to do it at one sitting under an anæsthetic. The latter, *me judice*, is not always a safe proceeding. I have seen two cases doing well up to this time develop after this wholesale removal a fatal peritonitis.

Since 1904 I have removed the appendix in all cases operated on, except five, four of them abscess cases. I never leave it now if I can see or easily feel it; only when I think that a search for it would endanger the patient's life, or when the obvious sloughing and suppuration have apparently already destroyed it, do I not attempt to remove it. Gauze packing gives one a very free hand in this respect—most removals can now be safely accomplished. It is very necessary to remove all stercoliths. I have known a portion of one accidentally left cause an abscess a year after the first operation when the appendix itself was taken away. With reference to secondary abscesses, except for one of the liver (in private) and one subphrenic one, I had had till recently in all my hospital and private cases but two, both near the seat of operation; but in the last month it has been my lot to meet with two more: one in this hospital two weeks after the original operation, when the patient was apparently well, necessitating a second laparotomy, and another (in private) which burst through Douglas's pouch. This latter was due to the large drainage-tube coming out prematurely, an accident that was not discovered for some 12 or more hours. All except the case of liver abscess recovered. One private case, however, had a very enduring fæcal fistula due to some sloughing of the cæcum away from its connexion with the appendix. The fæcal fistula which follows sloughing of the appendix itself is practically nearly always of a temporary nature.

About a month ago I had to deal here with an epidemic of acute cases of appendicitis, operating on no less than ten emergency cases, six in 24 hours. There were, I think, three other cases, making in all 13 in three days. All recovered. Appendicitis often seems to come in epidemics, and I think I have noticed that such epidemics follow some weeks or months after epidemics of influenza of the intestinal variety, but of this I am not sure.

In conclusion, gentlemen, I think I may say that if such acute cases are treated, as I submit they should be, by early operation, when once the condition is clearly diagnosed, the mortality of such early operations, although done during the attacks, should not be, and will not be much, if at all, greater than those done between attacks; in other words, I attribute the present mortality of operations during attacks almost entirely to delay, and against that delay I would wish to protest, and looking at its evil consequences to warn you and others who, in the future, will see this dangerous and insidious disease in its early stages.

An Address

ON

MODERN PROGRESS IN OUR KNOWLEDGE OF THE PATHOLOGY OF GENERAL PARALYSIS.[1]

Delivered before the Hamilton Medical Society, Ontario, on April 14th, 1909,

BY ERNEST JONES, M.D., M.R.C.P. LOND.,

DEMONSTRATOR OF PSYCHIATRY, UNIVERSITY OF TORONTO; PSYCHIATRIST TO THE GENERAL HOSPITAL, AND PATHOLOGIST TO THE HOSPITAL FOR THE INSANE, TORONTO.

THE remarkable progress in our knowledge of the pathology of general paralysis that has been achieved in the past six or eight years is of equal importance from both a theoretical and a practical point of view. On the theoretical side it has thrown much light upon the pathogenesis of a striking malady and has explained much of the actual mechanism of various obscure morbid processes, while on the practical side it has served to clarify our ideas about the boundaries of the disease known as general paralysis, to define sharply the disease, to settle the vexed problems of its etiology, and, above all, to provide us with ready means for making an accurate diagnosis at an early stage of the affection.

Our knowledge has expanded in two main directions, histological and chemical, and although the latter will principally be dealt with here I shall first say a little about the former. Thanks to the labours of Nissl and Alzheimer we now have an anatomical picture of general paralysis as precise and characteristic as any in the range of pathology, and this very fact alone, that we can by an anatomical examination mark off the affection from those resembling it, is of the greatest practical interest. We are to-day in a position completely to disregard the clinical diagnosis of a given case and unhesitatingly to proclaim from only the histological characters of the brain whether it was or was not a case of general paralysis during life.

It would be impossible here even to enumerate all the histological changes found in this affection, let alone to discuss the difference between them and those found in other affections, and I will simply give a rapid review of the changes in the cortex that may be considered most characteristic.

In the *pia* the most striking feature is the intensity of the infiltration and the great variety of cells present. Of these the chief are lymphocytes, plasma cells, and mast cells. The infiltration is thus not confined to one kind of cell, as is the case with tertiary syphilis. The pial changes are essentially infiltrative and not hyperplastic, as is in many other diseases. They cannot be correlated with the cerebral changes as they can in tertiary syphilis, for in general paralysis the pial and cerebral changes run an independent course. The plasma cell, the recognition of the distribution of which is so important in making a histological diagnosis of general paralysis, has the following features. The nucleus is enclosed in a thick membrane and rarely shows mitosis. The protoplasm is metachromatic, is darker at the periphery than around the nucleus—where it is often yellow—and gets lighter as the cell ages; it often shows vacuolation and degenerative changes.

---

[1] The address was illustrated by microscope and lantern slides, and was accompanied by a demonstration of the chemical tests referred to.

The *ganglion cells* show all stages of degeneration and sclerosis. The most marked change is the destruction of the orderly arrangement of the different cell layers, which occurs to an extent never met with in any other condition.

The *glia* proliferation is very diffuse and extreme. It differs from that found in other diseases in the rich formation of large thick fibres which are intimately connected with the vessel sheaths. The superficial layer of the cortex is especially affected. Another characteristic feature is the appearance of giant glia cells, which otherwise occur only in cases of luetic endarteritis.

The destruction of the *myelin sheaths* and the secondary degeneration is marked by its widespread extent and intense degree.

The most characteristic changes in general paralysis are, however, in the *blood-vessels*. These show the most extraordinary proliferative activities, and throughout the cortex a number of new vessels are formed by the process of budding. The new formation is not confined to areas of softening, as it is in most diseases. The vessel intima is greatly thickened and vascularisation is often found in it. The adventitia is similarly thickened but the media only slightly. Cell proliferation is thus confined to endothelial and adventitial cells. The change that has the greatest diagnostic import is the character of the infiltration of the lymph sheath of the adventitia, the space of which is very greatly dilated. Here we find an enormous infiltration with both lymphocytes and plasma cells; other cells, such as mast cells, may also be found, but not *Körnchen* cells. *Körnchen* cells, which carry the fat, play an opposite rôle to plasma cells and lymphocytes, for they are found in the vessel sheaths in arterio-sclerosis and only in softened areas in general paralysis, whereas plasma cells are found in both vessel sheaths and softened areas in arterio-sclerosis and only in the vessel sheaths in general paralysis. Outside of, and attached to, the vessel walls in general paralysis are found the curious *Stäbchen* or rod-shaped cells; these occur in no other disease, at least not in the typical elongated form. Side by side with all these proliferative changes in the vessel wall are found some of a retrogressive nature, such as degenerations, of which the hyaline form is the most frequent. These are, however, always less pronounced than the proliferative ones, and never dominate the picture as they do in various forms of arterial disease.

The picture made up by the above details is one that is never found in any other disease, so that, as was before mentioned, we can with absolute certainty say whether a given brain came from a case of general paralysis or not.

We now come to the progress that has been made in the clinical pathology of the disease, and this is almost exclusively concerned with the examination of the cerebro-spinal fluid. The operation of lumbar puncture is so simple that I will not take up your time with any description of it, though I may add a few additional points that experience has shown to be important. The interval between the fourth and fifth lumbar spines is preferable to that between the third and fourth, as being wider. An iridium needle is preferable to a steel one, as being less liable to break. One should never withdraw more than at the most 10 cubic centimetres of fluid at a time. The sitting posture is more convenient in the case of lunatics, as it is then easier to keep to the middle line if they move at a critical moment. The patient should invariably lie down immediately afterwards for the rest of the day. Lumbar puncture should not be performed in a case of tumour of the brain. If these precautions are observed, and strict asepsis ensured, then it may with confidence be stated that there is no risk of any complication or danger arising as the result of the operation.

A large number of characters of the cerebro-spinal fluid may be examined, but only three are of any great practical interest and diagnostic import. They are the pressure of the fluid, the proteid content, and the cytological features. The pressure of the fluid may be measured by allowing it to flow into a bent tube containing saline and observing the height of the rise in the vertical arm of the tube. The value which this observation has in diagnosis is chiefly a negative one—that is to say, the finding of an increased pressure is not a specially weighty piece of evidence in favour of the diagnosis of general paralysis as it may be made in several other affections, notably in tumour of the brain; on the other hand, as an increased pressure is so remarkably constant in general paralysis one would be very chary of making a diagnosis of the disease if the pressure were not raised. The rise in pressure may be very great; I have punctured several cases of general paralysis in which it was over 800 millimetres of mercury.

The proteid[2] of the normal cerebro-spinal fluid is exceedingly slight in amount. It is chiefly, and perhaps altogether, of the nature of globulin. In general paralysis the amount of proteid is increased often four or five-fold. Albumin is constantly present, but probably the main bulk of the proteid is globulin. There are a considerable number of different kinds of globulin, but the main interest in general paralysis centres round one variety which is known as euglobulin. This is so because not only is it present in the cerebro-spinal fluid of general paralysis in considerable quantity, but especially because it is now known to be the carrier of the interesting antibody that is operative in the Wassermann reaction of which we shall speak in a moment. Euglobulin differs from serum globulin in several particulars, the chief one being that it is precipitated in a 33 per cent solution of ammonium sulphate, whereas a strength of 50 per cent. is necessary to precipitate serum globulin.

Of the chemical tests for proteid used in this connexion some give a positive reaction with both the normal fluid and that of general paralysis, though in a much more pronounced way in the latter case, while others give no positive reaction in the normal. Of the first class, the two of most convenient application are those generally used in testing for the presence of proteid in urine—namely, the heat and the nitric acid test. In the former instance, the fluid is first acidified, and it is then better to boil the whole length of fluid instead of only the upper part as is done in the case of urine. The Heller nitric acid test is applied in the usual way by gently running some fluid on to the upper surface of cold concentrated nitric acid. By these tests only a trace of proteid is found in the normal, while with general paralysis the precipitate or ring formed is of a considerable density.

Of the second class of tests I will here mention only two. The first was described a few months ago by Noguchi o New York and is carried out by adding half a cubic centimetre of a 10 per cent. solution of butyric acid in physiological saline to a tenth of a cubic centimetre o cerebro-spinal fluid and heating the mixture to boiling point. A tenth of a cubic centimetre of 4 per cent. sodium hydrat is then added to the mixture which is again heated. Whe the reaction is positive there appears within half an hour no only a white cloudiness, which is of no significance, but peculiar flocculent precipitate. The second of these test was described by Dr. G. W. Ross and myself in a paper rea last January before the Ontario Academy of Medicine,[3] and since that time we have had considerable opportunity of verifying the conclusions there advanced. It consists in gently pipetting some of the fluid on to a saturated solution of pure neutral ammonium sulphate. A positive reaction is manifested by the appearance of a characteristic, thin sharp white ring at the junction of the two fluids; this within a few minutes assumes a fine mesh aspect. These two tests are constantly positive in cases of general paralysis; they are sometimes so in cases of tertiary lues of the nervous system, but they are always negative in all other forms of mental disease and in the normal.

The cell content of the fluid should be studied in two ways. First, an absolute count should be made, and this should be stated in terms of cells per cubic millimetre and not in terms of cells per field as is often done. For this purpose it is unnecessary to centrifugalise the fluid. The Fuchs-Rosenthal special counting chamber may be utilised, or the ordinary blood-counting chamber may be used by a still simpler method

---

[2] A full account of this subject is given in "The Proteid Content of the Cerebro-spinal Fluid in General Paralysis," Review of Neurology and Psychiatry, June, 1909.

[3] On the Use of Certain New Chemical Tests in the Diagnosis of General Paralysis and Tabes, Brit. Med. Jour., May 8th, 1909, p. 1111.

I described some two years ago.[4] Secondly, a differential study of the cells should be undertaken. In meningitis this can be done with sufficient accuracy during the absolute count by simply noting the relative frequency of mononuclear and polymorphonuclear cells. In general paralysis, however, a special procedure is necessary so as to permit of a more precise study of the different kinds of cells present. By far the best method for this purpose is the one introduced by Alzheimer. Two volumes of 96 per cent. alcohol are added to one of the cerebro-spinal fluid; the deposit obtained after centrifugalisation is hardened in alcohol and ether, and sections cut and stained along recognised lines.

In the normal cerebro-spinal fluid cells are rare. One never finds more than five to the cubic millimetre, and they are practically always to be classified as small lymphocytes. In general paralysis the cell count is almost always increased. The diagnostic significance of the increase varies with its extent. A count of 40 to 50 cells is not infrequently met with in tertiary syphilis, though in no other chronic disease except general paralysis—including, of course, tabes. A cell count of over a hundred, and I have met with counts as high as a thousand in this disease, occurs in no affections except general paralysis and acute meningitis.

The most striking feature of the cytological picture in the cerebro-spinal fluid of general paralysis is, next to the number of cells present, the great variety of them. It is rare in any other affection to find more than two or three different types of cells, but in general paralysis the number of different types is so great as to be indeterminate. The cell most frequently met with is, as in the normal, the small lymphocyte; usually two-thirds of the cells present are of this nature. Other important kinds found are polymorphonuclear cells, plasma cells, endothelial cells, phagocytes and mast cells, usually in this order. The cell picture of the cerebro-spinal fluid in general paralysis is, then, a highly characteristic one.

We have last of all briefly to mention the sero-diagnosis of general paralysis. I have time here only to outline this in the most sketchy way, but those who are interested may be referred to a review of the subject I have just published in the April number of the *American Journal of Insanity*.[5] Of the different methods that have been suggested only two will here be mentioned—the Wassermann-Plaut and the Porges-Meier. The essence of the former method consists in testing whether the cerebro-spinal fluid can combine with syphilitic material to bind the complement present in normal serum. Whether the complement is bound or not is ascertained by noting whether the mixture is able to dissolve the red blood cells of any animal in the presence of a hæmolysin that is specific for these cells. If the mixture can do this, then the complement, which is necessary to act with the hæmolysin in bringing about the solution of the cells, must have been still free, so that no special substance capable of fixing it could have been present in the cerebro-spinal fluid that was tested. On the other hand, if the red blood cells are not dissolved, then the complement must have been previously fixed by some substance in the cerebro-spinal fluid and the reaction is called a positive one.

The practical value of the test is very high. The reaction is positive with the cerebro-spinal fluid in general paralysis in 95 per cent. of the cases, and with the blood serum in 100 per cent. One would therefore refuse to make the diagnosis of general paralysis if the blood serum gave a negative Wassermann reaction. A positive reaction with the blood is, of course, not very strong positive evidence of the presence of general paralysis, for it occurs in three-quarters of simple syphilitic cases. On the other hand, a positive reaction with the cerebro-spinal fluid is strongly indicative of the presence of general paralysis, for it only rarely occurs with simple syphilis, even if this has caused serious disease of the nervous system.

The substance in the cerebro-spinal fluid that is responsible for the reaction is now known not to be a specific antibody, as Wassermann supposed, for it can fix complement in the presence not only of syphilitic material but also of many other substances. These are all, like lecithin, of a colloid nature; and it is probable that they are present to a large amount in syphilitic material. Still the fact remains that the supposed antibody is specific in the practical sense of being present only in individuals who have had syphilis, so that it is in some way produced, whether directly or indirectly, by the syphilitic infection. As was mentioned above, it is known that this substance is carried in the englobulin of the blood serum or cerebro-spinal fluid, and the further interesting discovery has been made that it is present in small quantities in normal individuals, though for special reasons it exerts no complement-binding capacity in them.

The fixation of complement that is the essential feature of the Wassermann test is performed by a reaction between this globulin antibody and colloid present in syphilitic material. The reaction has been shown to be of the nature of a precipitation, and Porges has suggested that one should be able to determine the presence of the globulin antibody by noting whether the cerebro-spinal fluid containing it causes a visible precipitate when added to a colloid emulsion. Lecithin is the colloid most often employed for this purpose, though sodium glycocholate gives rather better results. This test gives positive results in the majority of cases of general paralysis, but unfortunately it often does so also in other diseases, so that, though the theoretical interest of it is considerable, its practical value in diagnosis is but slight.

To sum up the advances in knowledge that have just been referred to, and the applications, both theoretical and practical, that may be made of them, the most striking corollary we see is the proof that the term "general paralysis," instead of being rather indefinitely applied to a vague group of allied states, as was formerly done, must now be restricted to a perfectly definite and sharply marked-off disease having both anatomical and clinical differential features of the most characteristic kind. Reflexion on the specific and highly differentiated nature of these changes at once makes it evident that in studying the etiology and pathogenesis of them we should expect to find a similarly specific cause. In the same way that discovery of the histological unity of tubercles made it practically certain that there was a specific cause at work, which was then discovered in the form of Koch's bacillus, so in general paralysis does the discovery that the disease is a specific unity that can be sharply differentiated from other diseases make it equally certain that there must be here also a specific cause at work. What that cause was had for some time been surmised as a result of the huge mass of converging evidence, drawn from the most diverse sources and following the most diverse lines of argument, that unequivocably pointed in only one direction. This surmise has within the past few years been most strikingly and gratifyingly confirmed by the study of the cerebro-spinal fluid, which showed, on the one hand, that an increase in proteid and a pronounced lymphocytosis occurred in no diseases except syphilis and the affections of tabes and general paralysis that are presumably a sequel of this, and, on the other hand, that highly peculiar substances, the so-called antibodies, are present in every case of general paralysis and in no other affection except syphilis.

The exceedingly high value that the new observations have in enabling us to make an early and certain diagnosis of the disease I have already alluded to, and in this paper, which is of a necessarily discursive character, it is impossible further to deal with the question or with that of the increased understanding of the pathological mechanisms at work that we have similarly attained. I will conclude with a remark of a more general nature—namely, that I am greatly impressed with the danger there is in tending to regard general paralysis as a paradigma of mental disease. This tendency is an extremely natural one, because it is so harmoniously in accord with the over-materialistic training we have all received in medicine in general and in psychiatry in particular. The pathological discoveries I have referred to seem so conclusively to confirm the common medical belief that mental disease is always due to some primary physical change in the brain produced by some poison circulating in the blood that those of us who, like myself, are convinced of the fundamental falsity of this belief are tempted at times to regret the making of these discoveries, magnificent as they are. At all events I feel sure that they will set back the clock in the development of scientific psychiatry more thoroughly than any other event that could have happened. This opinion is founded on the view that general paralysis, instead of being the type of the way in which mental disorder is produced, represents an exceptional way. I am not hopeful that histological and chemical methods, pursued along the route that has been opened up in such an apparently obvious way, will throw light upon many more psychiatric problems, with the exception perhaps of certain forms of acute toxic psychosis. Greatly as I admire the precise and valuable results that have been reached in the case of general paralysis, I consider that the psychological work done by, for instance, the Freud-Jung school is not only more valuable at the present moment, but is infinitely more promising of fruitful results for the future.

THE INTRAMUSCULAR TREATMENT OF SYPHILIS, WITH SPECIAL REFERENCE TO THE INSOLUBLE PREPARATIONS OF MERCURY: A CRITICAL REVIEW.*

BY GEORGE PERNET, M.D. PARIS, M.R.C.S. ENG., L.R.C.P. LOND.

THE protean manifestations, direct and indirect, of this infection meet the medical man at every turn, so much so that it may be said to dominate human pathology. Some writers have gone so far as to estimate that a third of the morbid conditions met with are accounted for by syphilis.[1] Notwithstanding the great advance made in recent years in the direction of prevention, syphilis is spreading, thanks to the increased intercourse of nations with one another and rapid means of communication. Wars, too, are accountable for an increase in the incidence of the disease, so much so that in South Africa, for instance, syphilis has become a danger to the community.[2] The moving about of large bodies of troops necessarily leads to the spread of venereal complaints, and I need not recall the great outbreak of syphilis at the time of the siege of Naples at the end of the fifteenth century. I have no doubt that the Cuban and Philippine campaigns have led to the spread of syphilis in the States. Again, the doubtful blessings of our civilisation can be bought too dearly by native races, such as those of Uganda, among whom lues venerea has become rife and threatens to exterminate,[3] a recent example among many of syphilis conveyed to hitherto non-contaminated communities, as in the case of Pacific islands, for instance, infected by the early navigators. Where various preventive measures have been tried, some of them most drastic, they have defeated the very ends they were intended to attain by encouraging a security that was illusory.

I have mentioned these points, not by way of an apology for dealing with a subject of perennial interest, and likely for a long time to come to partake of that character, but to show that as far as syphilis is concerned we have a Sisyphean task before us. If we turn now from generalities as to distribution and spread to the particular, the individual, we find the domain of the disease being daily extended and to include every tissue in the body. Since the days of John Hunter, who by his great authority put the clock back as to our knowledge of visceral syphilis,[4] although Morgagni had demonstrated the fact of its existence, one structure after another has succumbed to investigation. I would here insist on the enormous importance of recognising that the syphilitic infection is one that may affect any organ of the human body, and that the possibilities of future mischief are great, however benign the early visible manifestations of disease may appear to be.

It is germane to my subject to detain you yet a little longer on some cardinal points, which must, in my opinion, ever be borne in mind. We do not treat an abstract thing called syphilis, but a human organism suffering from the invasion of another organism, the *Spirochæta pallida* or *Treponema pallidum*. That this organism must be accepted as the *causa causans* is, I think, settled. Every individual case must be treated on its merits. I have dealt with this at large in another place,[5] but to prevent any misunderstanding I desire to say, *in limine*, that intramuscular injections, whether of soluble or insoluble preparations, are but one means, and a very valuable one, of treating the infection. Personally I am eclectic, and much depends on circumstances of various kinds as to the method to be employed. Intramuscular injections, especially the insoluble ones, are not to be used in a routine manner for any and every case of syphilis. It is this routine, and, I may add, careless, manner of applying an otherwise admirable method that has been responsible for such undeserved disrepute. This is a point I shall have to go into at greater length later on. Another point, which I think should be thoroughly grasped once for all, is that treatment should be started immediately the primary chancre is recognised as such, without waiting for so-called secondary or general manifestations. Indeed, all our powers should be directed towards the prevention of such symptoms by early energetic treatment guided by due and proper supervision of the case. Again, treatment should be pursued with perseverance and for a long period, for it has been amply demonstrated that inadequate treatment in the early years of the infection is fraught with future danger. It is now almost generally accepted as a fact, and further investigation serves but to confirm, that tabes[6] and general paralysis are syphilitic in origin.

Various changes in the blood-vessels[7] leading to early and serious complications, unrecognised gummata of the heart terminating with sudden death, and so on, must be mentioned here. One of the latest conquests of syphilis is the involvement of the "band of His," giving rise to what has been called "heart block" or the Stokes-Adams syndrome—viz., incoördination in the rhythmic movements of the auricles and ventricles. Rénon[14] records an instance in a syphilitic patient, who was distinctly relieved by pushing intramuscular injections of enesol.[8] That cancer may develop as a result of syphilis is undoubted, especially since the work of Fournier, Butlin, and others concerning cancer of the tongue. Gaucher goes so far as to consider this condition as being always syphilitic in origin.[9] Recent investigation again points very strongly to malignant disease of the uterus as a possible consequence of the syphilitic infection.[10]

Sufficient has been said in these brief introductory remarks to demonstrate the seriousness of the question of treatment, and is my excuse for calling your special attention to the intramuscular method. I am well aware that as far as the soluble preparations are concerned their employment is well known to you here in the United States, and it is not my intention, therefore, to detain you long as regards them. On the other hand, the insoluble preparations have not, if I may use the term, "caught on" either in my own country or in the United States—that is, as far as my knowledge goes concerning the latter, whereas in France these preparations are in current use. In England it is true, thanks to the efforts of Colonel Lambkin, mercurial cream injections are used in the British army, notwithstanding the adverse criticism of many well-known British dermatologists given in evidence before the Commission of Inquiry,[11] although apparently they had had no actual experience of the method. Judging from the discussion that took place on the subject at the Sheffield meeting of the British Medical Association (Dermatological Section) last year this attitude is maintained, for Professor Neisser of Breslau and myself were the only two speakers who were resolutely in favour of the use of the insoluble preparations.

Now this negative attitude as regards a valuable method is explained by the fact that several fatal cases have been recorded as a result of the use, or more correctly the misuse, of "grey oil." It is therefore incumbent on me to examine some of these cases critically before going any further. In 1906 Claude and Dobrovici[12] published five fatal cases following injections of grey oil. I will take them seriatim.

CASE 1.—A woman of 50 years. Injections of grey oil were given, but there are no details of this case. The patient succumbed to gangrene of the pharynx.

CASE 2.—A labourer of 25 years. Syphilis recent. He had four injections of grey oil during the month he was at the Hôpital Ricord. Was admitted to the Hôpital Saint-Louis with stomatitis. No albumin in urine. At the necropsy no evidence of pulmonary tuberculosis. Necrosis of left lower maxillary.

In this instance no details as to doses injected are given. Howbeit, the fatal issue certainly appears to have been due to the injections.

CASE 3.—A café wa[illegible] Sept. 17th, 1904, to Saint-Louis for bad [illegible] philis. Was treated for mental symptom[illegible] and epileptiform convulsions at another Paris hospital, receiving two series of six injections each with an interval of two months between them—viz.,

better as
red in the
njection of
tion) with
o g imma
n stopped
lungs was
soft with

In this case we have a tuberculous patient, with kidneys no doubt much below par leading to renal inadequacy The occupation makes alcohol a possible unfavourable factor Another point is the fact that he was ordered iodide of potassium, which increased elimination of the insoluble mercury preparation stored up in the body, for the last injection of the second series of six had been administered ten days before admission to Saint Louis In mercurial stomatitis iodide of potassium is in my opinion contraindicated, but in this particular case the gumma of the anterior pillar must be borne in mind The exhibition of saline aperients is usually the best way of dealing with mercurial stomatitis, in conjunction with local treatment To sum up, this case is one in which intramuscular injections of an *insoluble* preparation were distinctly contra indicated from the first, and shows the necessity of dealing with cases on their individual merits after a thorough overhauling The upper third of the right lung showed excavations, and would of itself have been sufficient to contra indicate absolutely the employment of grey oil injections [13]

CASE 4 — A woman of 50 y
weekly injections of 6 to 7 cen
plegia externa which it shou
treatment Treatment was
was discovered about the las
all kinds of treatment the
patient was admitted to the
June 12th There had been some albuminuria The apices of both lungs revealed *encysted tubercles* one of which was caseating Broncho pneumonia The kidneys were sclerotic with adherent capsules and atrophied cortices

In this case a more thorough examination (urine, lungs) would have prevented the use of intramuscular insoluble injections, especially in the case of an elderly female, for women do not stand the insoluble preparations as well as men, nor in such large doses

CASE 5 — A woman of 25 years syphilitic was treated in a Paris hospital in May 1906 with grey oil After an examination of the urine which did not contain albumin 10 centigrammes of metallic mercury were injected A w

Here, again, the intramuscular injections were evidently responsible, but it should be pointed out that 10 centigrammes was too large a dose to start with in a woman, and, moreover, if the mouth had been examined for signs of stomatitis as it should have been in a routine way, the second injection of 5 centigrammes would not have been given

It must be noted that these five cases were hospital patients and it is only fair, I think, to assume that their nutrition was below the average Another point of paramount importance is the condition of the teeth and mouth In Europe the teeth of hospital patients are frequently in a very bad state, in many cases the use of a tooth brush being unknown In the five cases I have rapidly summarised the teeth are not mentioned Possibly too although it is not stated, the stomatitis may have been aggravated in some of the cases, besides Case 3, by the exhibition of iodide of potassium

In addition to these five observations I would call your attention to some other bad cases which led to discussion at the Société Médicale des Hôpitaux de Paris [14] in 1906 A woman, aged 38 years, admitted on March 22nd, 1906, under Ménétrier and Bouchaud, developed a severe stomatitis of five weeks' duration five months after the injection of calomel The teeth were in a very bad condition She was discharged improved on April 1st She returned on April 12th with a fresh outbreak of the stomatitis, when a nodule in the right buttock was discovered It appeared she had had an injection on the left buttock in March, 1905 followed eight days later by an abscess which was opened, leaving a scar A second injection was made into the right buttock in October, 1905, leaving a nodule or infiltration, which was excised. The urine did not reveal any albumin, but mercury was found in it In this case the injection had been made in the subcutaneous fat and not into the actual muscle as it should have been *This is an important point*, and it is necessary in fat patients that a needle of sufficient length should be used to ensure reaching the muscle

In another fatal case, recorded by Letulle,[15] a woman, aged 26 years had had 20 injections of grey oil extending over four months, the patient being pregnant at the time All went well at the confinement and a full term child was delivered On March 24th, the day before her admission to hospital, another injection of grey oil was made, making 21 injections in all A few hours later acute stomatitis occurred The doses of the grey oil injected were unknown, as usual Her teeth were in a deplorable condition, they were never attended to in any way during her confinement Several decayed teeth were removed, with some improvement But the stomatitis returned and the patient died At the necropsy slight nephritis of some standing was found Here we have to deal with an unjustifiable use of an insoluble preparation —viz , 20 injections in four months in a pregnant woman It is well known that mercurial stomatitis is very likely to occur in pregnancy and the puerperium when the woman is in a toxic condition already [16] Pregnancy contra indicated the insoluble injections Moreover, women are in any case more prone to develop stomatitis than are men [17] The doses injected were not known, a fact which crops up frequently in the records of fatal cases In addition, the patient's teeth were evidently in a condition that should have been an additional contra indication to the employment of insoluble injections

In the discussion Queyrat, who had had a large experience *at Cochin Ricord, said he had never seen any serious* symptoms following the use of intramuscular injections of grey oil, even in larger doses than was usual, although 6000 and more a year were carried out in his department He pointed out that in some individuals nodules occurred, and in such it was wise not to persevere with insoluble preparations if nodules followed the injections on two consecutive occasions In this I agree, for it must be remembered that in cases of that kind a large amount of mercury may subsequently be suddenly thrown into the system In some cases deposits of mercury have been revealed by X rays [18] and excised, thus cutting short the stomatitic symptoms

Duhot, who for some years now has employed the insoluble preparation of mercury on a large scale and followed up his cases in a very thorough manner, has published his results in a recent paper [19] As regards "grey oil,' during the three years 1906-7-8 he has dealt with 781 cases of syphilis (primary, early and late congenital) in hospital and private practice (some 7800 intramuscular injections) and including cases previous to 1906 has had an experience of over 20,000 injections in all Taking the year 1908 (289 cases in hospital and in private 253—141 hospital and 121 private of which were treated by means of injections of grey oil, about 4500 injections) he never met with any serious complication as a result of the intramuscular treatment ("*huile grise*') The doses varied from 7 to 14 centigrammes In neither class of practice was there any case of stomatitis In three hospital cases a superficial abscess was observed due to a fissure in the needle Here I may observe that needles (platino iridium) require supervision as to cracks, thus leading to a deposit of the grey oil in the superficial parts 15 nodules (10 hospital, 5 private) occurred By nodule is meant a nodular infiltration or small lump in the muscle Slight gingivitis 6 (4 hospital and 2 private) Thoracic pain or constriction 9 (6 hospital and 3 private), Mercurial grippe, "*grippe mercurielle*' "*fièvre mercurielle*' of Emery, that is general malaise, slight febrile manifestations, pains about the limbs and joints, loss of appetite,
headache, &c , in a
grippe [20] Albuminur
cases Intolerance
were observed in women, this emphasises what I have already said as to women not standing the injections as well as men

Jullien [21] was the first to contend that the early (*secondary*) manifestations of syphilis could be systematically prevented by energetic treatment—viz , by intramuscular injections of calomel Duhot held the same opinion for a time but subsequently he gave up calomel for grey oil, and he now puts forward 200 cases he has had under observation, and claims that as a result of energetic "abortive" treatment, as he calls it, by intramuscular injections of grey oil in large doses started immediately on the early diagnosis of primary chancre, there has been no sign of tertiary manifestations.[22] Of course, as we all know, the tertiary symptoms may be long delayed, and this is a fair objection that might be made as to the point he has put forward. As to doubt about the diagnosis of the primary syphilis, he has laid this at rest by a systematic examination for the Treponema *pallidum* by demonstrating its presence in smears and frequently in the excised chancre, this being ascertained in a routine way before starting the treatment. When the treatment was commenced after the appearance of the secondary or early rash, tertiary manifestations have occurred but they have been rare, thus emphasising the necessity of early interference. I have already insisted on the importance of such a procedure, but it will bear repeating again and again, so great is the influence of authority, especially as it is still maintained in some quarters that one should wait for the secondary rash before commencing treatment, although that attitude is slowly breaking down and giving way to a more rational view of the matter. Moreover, Duhot further insists that in his cases (134 at the time he wrote on the point) cerebro-spinal lymphocytosis as ascertained by lumbar puncture did not occur. In addition to this, Duhot, with the assistance of De Grave, is applying the Wassermann test to cases treated by the abortive method. They have found that the negative Wassermann test is in direct ratio to energetic early intensive treatment.

Scherber, in the clinic of Finger at Vienna, has also obtained encouraging results with the "*abortive*" treatment by excision of the primary sore and intramuscular injections of either mercury salicylate or "*huile grise*," but mainly the former.[23]

Neisser has also employed large doses of grey oil, following on Duhot's initiative, that is, 14 centigrammes. In a recent communication Zieler (now of Würzburg), working in Neisser's Breslau clinic, places on record that injections of large doses of grey oil are well borne, and states that in 50 cases treated in that way, totalling 271 injections of 14 centigrammes, no untoward complication was observed, and that even in the case of women such large doses could be frequently employed, but that in them marked infiltrations (nodules) were observed in several instances.[24] Zieler insists, however, on the importance of using the new preparations of grey oil in this respect, and points out, as I have already done, that women do not bear the injections as well as men, and that it is incumbent in their case to use smaller doses—viz., 5 to 7 centigrammes.

Another recent paper on the subject by Carle must also be alluded to. In 282 cases (1902 to 1907) Carle employed the abortive treatment early and "intense," with very satisfactory results as to secondary and tertiary symptoms,[25] and on the whole he confirms the results of Jullien, Duhot, Leredde, Tommasoli, and others; but Carle does not consider that abortive, intense, early treatment prevents in all cases subsequent morbid manifestations. He also expresses the opinion that in rare instances the iodides and arsenic are valuable, especially in the malignant forms.

It would be impossible in the present paper to go into all the literature of this big subject, but I think I have said enough to show that when the intramuscular injections of grey oil are carried out with care and with the precautions that I shall enumerate further on, serious complications do not arise. In the foregoing it has been my endeavour to deal with the matter fairly and squarely, for we must aim as medical men at doing all we can for the benefit of our patients. I have placed before you the dangerous possibilities that lurk in the treatment unless carefully applied, and I should certainly not advise any and everybody to attempt it unless the method has been mastered. I repeat once more that it is *not* a routine treatment which can be carried out in a haphazard manner.

As far as my own work goes, I may say that I have only employed the intramuscular injections of insoluble preparations in my private practice. I have never seen any complication arise. My results have been very satisfactory and I consider the method a most valuable one, especially when any serious syphilitic complication threatens. My experience of the *early abortive intense* treatment has been from the nature of private practice very limited, and I have not felt justified in applying it to its full extent. But where full control of the patient could be obtained I have found no ill-effects ensue after 10 or 12 consecutive weekly injections of doses varying from 7 to 10 centigrammes. Indeed, the results have been in a few instances of this kind very encouraging. In one case the primary sore was followed by high temperature in a patient who had previously suffered from malaria, and who, as is usual in such an event, considered the febrile condition of that nature. I considered the temperature was syphilitic, and on that assumption I injected grey oil, as I have stated, with the best of results. Since then several series of injections of grey oil have been given, and the patient has done extremely well as far as syphilitic symptoms are concerned. The injections have been well borne, although the patient had been liable to pseudo-dysenteric attacks. Salicylate of bismuth in gr. v. cachets three times a day is efficient as a rule in dealing with any tendency to attacks of diarrhœa.

Before leaving grey oil it is necessary to state that a properly made sterilised standard preparation should be used. As far as I am concerned, I have always employed French preparations and I have found them reliable in their action. Grey oil is now in the French Official Pharmacopœia. The formula is: purified mercury, 40 grammes; anhydrous lanolin, pure and sterilised, 26 grammes; medicinal oil of vaseline sterilised, 60 cubic centimetres. This is put up in small glass-stoppered bottles of 1 cubic centimetre of the preparation containing practically 40 centigrammes of mercury. I now use Lafay's standard preparation, but there are other good brands such as Vigier's, Roger-Cavailles's, &c. I am obliged to mention this, as it is of the greatest importance, as you will see, to use a uniform grey oil, for some of the accidents which have been placed on record have been the result of using much too large doses in error, and in one case of employing a preparation put up by a pharmacist who made a mistake in reading the prescription (Smirnoff's case) By employing a standard preparation of one strength and a syringe one is accustomed to, there is no chance of confusion and of errors, which may arise when different strengths and variously graduated syringes are used.

Accidents with grey oil, and also with calomel, have occurred—that is undoubted, and I insist on the fact. But accidents have also followed the use of soluble preparations and fatal cases have resulted from inunctions. With regard to the latter I will mention two cases. In the case of a very fat woman, G. Mayer[26] of Aachen records a fatal termination following the use of inunctions, which led to a severe generalised eczema, as he calls it, but which was probably what we should more correctly designate mercurial dermatitis. Stein[27] has quite recently given the details of a fatal case occurring in a young woman of 26 years, with recent syphilis, who developed severe dermatitis after 24 rubbings of 3 grammes each of unguentum hydrargyri, from Nov. 18th to Dec. 17th, accompanied by fever and very severe complications. The patient died seven weeks after the commencement of the treatment. At the necropsy, numerous punctiform hæmorrhages were found in the muscles of the trunk, in the endocardium, the liver, the kidneys, and the intestinal mucous membranes. It will be noted that once more the patient was a woman, a point to be borne in mind. There is no doubt the rubbing was over-done. Moreover, when the erythema started, iodide of potassium was administered, a proceeding which I consider a mistaken one—a fact I have already insisted on. These are not the only two cases that might be brought forward against the inunction treatment. But that would surely be no reason for damning a method that is valuable. Philosophically considered, everything is relative, just as much in medicine as in any other sphere of human activity and endeavour.

In my own experience I have found that patients suffering from the effects of fairly recent malarial and tropical infections, such as blackwater fever, bear inunctions badly. In one instance, two or three inunctions led to severe stomatitis, although the mouth had been put in order, and the patient was confined to his bed and kept under strict observation. *A fortiori* in such cases would intramuscular injections of insoluble preparations be contra-indicated, and soluble preparations would have to be closely watched. In the particular case I have referred to I found arsenic very valuable. That was before atoxyl, but they are the sort of patients in whom a properly prepared atoxyl should prove useful.

In connexion with my subject, I must allude to an instructive and unusual case of indirect mercurial intoxication terminating fatally and occurring in a tuberculous male of 21 years related by Volk. The patient was admitted to a venereal ward in Vienna on account of an ulceration which had been thought to be luetic but was really tuberculous. The cubic capacity of the ward was about 750 cubic metres and contained 24 patients. Five or six of these were being treated by means of Welander's mercury bags, whilst others at the time were not having inunctions or other external mercurial treatment. Nine days later the tuberculous patient developed mercurial stomatitis, and notwithstanding the fact that he was moved to another ward he rapidly sank with symptoms of lobular pneumonia and œdema of the lungs, the stomatitis having meanwhile become worse and worse.[28] Here we have a rare example of indirect mercurial intoxication, but it must be observed occurring in a tuberculous non-syphilitic patient.

This case reminds me of an instance of bad stomatitis in a male with old syphilis following inunctions. The stomatitis made no headway towards recovery when the inunctions were stopped and the condition treated by appropriate remedies, but I discovered that the patient was still wearing the singlet he had worn during the inunction period and which was still soiled with unguentum hydrargyri. He was inhaling mercurial vapours, especially at night. When this was removed his stomatitis soon improved. If I have referred to toxic complications arising from other methods, it has not been with the intention of condemning them, but in order to show that no method was perfect, and that intramuscular injections of insoluble preparations especially were not to be thrown on one side because accidents, in most if not all instances avoidable, had followed their use.

I take this opportunity of calling your attention to another point of importance—viz., that complications laid at the door of mercurial treatment are not infrequently really due to the syphilitic infection itself. This is a subject I cannot deal with in this place at any length, but symptoms of that kind, such as fever, albuminuria, and so forth, will readily occur to you. Moreover, this side of the question has already been thoroughly dealt with by Emery and Lacapere [29] and others, so I will pass on to the consideration of matters more nearly related to my present paper.

Having touched on grey oil, I must now say a few words on the subject of calomel, first employed subcutaneously and then intramuscularly by Scarenzio in 1864.[30] Jullien, who had experimented with a variety of mercurial preparations, soluble and insoluble, came to the conclusion that calomel in intramuscular injections was a sovereign remedy and one which, when used carefully, could be employed with safety. He instances, for example, two cases of early optic neuritis which cleared up under its use.[31] In serious manifestations of syphilis, of the brain, eye, and so forth, calomel is a sheet anchor. Leredde, Babinski, and other observers have shown its value in syphilitic affections of the nerves. Darier, in speaking of threatening specific cerebral arteritis, is very categoric on the point, and rightly so. He advises the immediate injection of 10 centigrammes of calomel in the case of men, and 5 to 7 centigrammes in the case of women, continuing them every fifth or eighth day, but when the mouth is in bad condition a daily injection of a soluble preparation (biniodide, benzoate, cyanide) is to be preferred.[32]

In the initial manifestations of early syphilitic hemiplegia the use of calomel may make all the difference in the future of a young man. I have myself seen a promising career wrecked by not keeping this point well in view. The patient was a young adult from abroad, whom I saw for the first time a year after the hemiplegia had become confirmed. In the quite early stages of his cerebral syphilis he had been treated in London by mercurial pills, an utterly inadequate treatment. When he came under my observation for the first time, a year later as I say, there was nothing to be done, the arm having become ankylosed at the shoulder-joint, with contractures. This case made a great impression on me. Now had this young man been injected with calomel from the very onset there is every probability the hemiplegia would have been averted. And it is all very well to say that the insoluble preparations may lead to complications in the way of mercurial intoxication, but in desperate junctures the consequences of the syphilitic infection, as in this case, may be more damaging still.

One of the objections made to calomel is that the injections are very painful. They may be, although patients vary a great deal in this respect. I have not found Zambeletti's calomel preparation lead to any pain, or at most it has been slight or very bearable. Recent experimentations by Lévy-Bing, Eudlitz, and Lafay tend to show that concentrated calomel preparations are better borne than those usually employed. They have settled on a preparation containing 40 centigrammes to 1 cubic centimetre, instead of using those in the market containing only 5 or 10 centigrammes to 1 cubic centimetre.[33] This dosage has the further advantage of assimilating it to the "*huile grise*" of the French codex, thus leading to simplification in practice.

There is a syphilitic symptom which is of great importance and not infrequently overlooked, I mean the characteristic headache coming on towards the evening (vesperal), or occurring at night (nocturnal), and which calls for energetic and immediate treatment by means of intramuscular injections of insoluble or soluble preparations, as the case may be. In dealing with the insoluble preparations, and especially "grey oil," I have referred mainly to French medical literature, for the simple reason that it is in France that they have been mainly employed. In England and the United States this method of treatment has not been applied to any extent, but only made use of sporadically.

Although I have subtitled my paper a critical review, one of its objects is of the nature of a plea in favour of valuable preparations likely to prove of the very greatest service in combating so fell and protean an infection as syphilis, and in preventing some of its direst consequences, disastrous alike to the individual and the community. I make no apology, therefore, for bringing the matter before you, and I am sure that with your active American minds, so quick to seize on the practical aspects of life, you will have grasped the force of the evidence which I have placed before you. I have done this in a fair and impartial manner, being fully alive to the responsibility which such a presentation entails. This fact makes it necessary that I should detain you yet a little longer in order to touch on the technique of the insoluble injections.

In dealing with this part of my subject to save time I will give the details of the manner in which I myself carry out the intramuscular injections, but in the bibliography which I have appended references will be found by those wishful of going more thoroughly into the matter; indeed, it is very desirable that anyone contemplating the employment of the method should make a point of doing so.[34] For the insoluble preparations the Edmond Fournier and the Lévy-Bing-Lafay syringes should be used and not an ordinary Pravaz, as usually recommended. The Fournier model is all glass and of ½ cubic centimetre capacity, divided into ten on the barrel, so that each division represents 2 centigrammes of mercury or of calomel, the standard preparations being, as I have said, 40 centigrammes of mercury to 1 cubic centimetre (*huile grise*) and 40 centigrammes to 1 cubic centimetre (concentrated calomel preparations) respectively.

The Lévy-Bing-Lafay syringe has been specially devised for the 40 centigrammes to 1 cubic centimetre preparations. It is all glass and nickel with bayonet adjustment for the cap, making the parts readily detachable. In this syringe the piston rod itself is graduated, being divided into 15, each division representing 1 centigramme of the 40 centigrammes to 1 cubic centimetre preparation (*huile grise* and calomel), thus rendering the instrument very practical. Fifteen centigrammes is the maximum dose that may in certain very special cases be employed without producing toxic effects, but I would warn you that it is advisable to be satisfied as a rule with doses not exceeding 10 centigrammes for men and 5 to 7 centigrammes for women.

As to the Zambeletti preparations of calomel they are put up in phials containing 5 to 10 centigrammes of calomel, so that any good ordinary glass syringe can be used. The syringes are sterilised by boiling in the usual way. As to needles, they are of iridized platinum with gold mounts, and can be passed through a flame before fitting to the charge syringe, but I prefer to boil them at the same time as the syringe. Their length is an important matter in the case of the insoluble preparations with which I am at present concerned—viz., not less than 5 centimetres. But needles of various lengths are required: 6, 7, 8 centimetres for fat subjects, in order to get the preparation well into the muscle. The bevelled end must be kept sharp to avoid giving pain. This is effected by means of small pieces of Arkansas stone. The lumen must be sufficient, but not too large. The needles can be kept in paraffinum liquidum or in alcohol. Before using them their permeability must be ascertained.

With regard to the parts of the buttocks where the injections are to be made I have come to the conclusion that an area round a point midway between the gluteal cleft and the anterior superior iliac spine is the most useful. Lévy-Bing[35] has gone into the matter by means of actual dissections and gives the following directions. Through the middle of a line joining the gluteal cleft and the anterior superior iliac spine he drops a perpendicular, and describes a circle with its centre at the point of intersection and with a radius of three centimetres. In each of the quadrants thus formed he makes an injection. There are also other suitable positions,[36] but the point is, to keep to the upper parts of the buttocks well away from the danger zone of vessels and nerves, which can be readily ascertained by a reference to anatomical plates[37] or to bodies in the dissecting room.

The following is the *modus operandi*. The injections should be made with the patient lying on a couch in the prone position. The part of the buttock selected must be thoroughly sterilised (soap, ethereal soap, alcohol, ether, and so forth). The sterilised needle is then attached to the nozzle of the empty sterilised syringe and plunged perpendicularly and rapidly through the skin into the subjacent muscle. The piston is gently drawn up two or three times in the barrel in order to make sure that the point of the needle has not penetrated a vessel. If any blood appear the needle may be either withdrawn a little and the test repeated or withdrawn altogether and another spot selected. It is, I need scarcely add, important *not* to inject an oily preparation into the lumen of a vessel. Personally, I have never drawn blood up in the syringe on applying this preliminary test, but nevertheless I always make the trial as a matter of routine. The barrel is then detached from the needle, which is left in place. The "*huile grise*" or calomel is then drawn up into the barrel directly from the *flacon*, an easy matter with Edmond Fournier's small calibre syringe. Here it is necessary to point out that the mercurial preparations should be slightly warmed, not heated, and well shaken up before charging the barrel. The dose required, 5, 6, or more centigrammes, as the case may be, is then drawn up into the barrel, which is re-attached to the needle, and if no blood has appeared at the mount of the needle the dose is slowly but firmly pushed home in the muscle. Duhot recommended that after this has been done some air or a little sterilised saline solution should be drawn up into the barrel, detached for a second time for that purpose, and in its turn pushed home in order to clear the needle of any preparation remaining on it, and thus avoid leaving a track of grey oil when the needle is withdrawn. Tracks of this kind may lead to small superficial furuncles. I have always used air and I have never seen any untoward result ensue. There is no need to massage the part, as is sometimes recommended. The orifice is covered with a small piece of zinc oxide plaster or collodion and wool. A careful record should be kept of the quantity injected at each sitting and the point injected. In the case of these insoluble preparations one injection a week is the rule. The injections should be made in the right and left buttock alternately. In every case, and especially when the insoluble preparations are employed, the patient should be previously thoroughly overhauled as regards the state of his mouth, the condition of the urine as to albumin, &c., his weight estimated, and so forth. I have already insisted on the condition of the teeth, any defect being put right by a dental surgeon before starting the treatment. This is an essential point, and may mean everything as regarded the future course of the treatment. During treatment the urine must be watched, as also the state of the gums and buccal mucous membranes, by examination with the frontal mirror and reflected light, in order that any warning may bid you to stop the injections.

Again, I would insist that all methods have their advantages and disadvantages. In selection one must be eclectic and it is of the greatest importance not to go off one's head in favour of any one method to the exclusion of all others. Every case must be dealt with on its merits and the various circumstances surrounding it taken into account. Injections of insoluble preparations must not be employed in a routine manner for all and sundry. In some cases they are absolutely contra-indicated, as in old people, the broken-down, the bed-ridden, paraplegic, and those with renal inadequacy or presenting albuminuria, patients suffering from tuberculosis, lead-poisoning, or decidedly gouty, and alcoholics. I have already called attention to the unsuitability of cases suffering from the devitalising effects of malaria and tropical fevers, as also of pregnant women. One must be specially careful in the case of women.

On a variety of other points I would refer you for full details to the quite recent contributions of Emery and Chatin, whose exhaustive and thorough work will well repay study, and of Lévy-Bing, who has written a succinct monograph on the subject.[31] Although I have dealt mainly with the insoluble preparations of mercury, for reasons stated, I have no desire to minimise the value of the soluble salts. The latter are often of the greatest utility, and I would here testify to the good results I have obtained with the hypertonic benzoate of mercury as prepared in accordance with the directions of Professor Gaucher. There are also a number of mercurial solutions, which all have their place and with which you are familiar.

In conclusion, I desire to thank you, Mr. President and gentlemen, for the opportunity you have given me of submitting the foregoing remarks to your judgment and for the honour you have done me in inviting me to take part in the work of your great Medical Association.

N INVESTIGATION INTO THE ACTION AND USES OF FIBROLYSIN IN MIDDLE-EAR DEAFNESS

BY J. GAY FRENCH, M S LOND, F R C S ENG,
GEON IN-CHARGE OF THE EAR, NOSE AND THROAT OUT PATIENTS
REAT NORTHERN CENTRAL HOSPITAL ASSISTANT SURGEON TO THE
CENTRAL LONDON EAR NOSE AND THROAT HOSPITAL,
GRAY'S INN ROAD W C

N 1892 von Hebra[1] published the results he had obtained h a 15 per cent solution of thiosinamine in alcohol in treatment of lupus and cutaneous scars He used this ution by the injection method and showed that it had a y [illegible] logical fibro cicatricial sue [illegible] which is chemically ow [illegible] prepared from oil of istard and occurs in colourless monoclinic or rhombic stals with a bitter taste and an odour of garlic It is an stable compound, insoluble in water, but dissolving freely alcohol The physiological action of thiosinamine is, in first place, to cause a diminution of the number of leuco tes in the blood, followed later by a very considerable rease Its action on scar tissue is very definite Macro-opically, after an injection a reddish scar, such as that er a burn, becomes paler, swollen, and more flexible, and limited movements of the parts bound down by the scar sue are increased in range, but after a short time these enomena disappear If, however, the injections are peated at short intervals it is found that the above ntioned conditions become permanent Microscopically, rgescence is seen to take place in the individual connective sue fibres, their outline becomes blurred and indistinct e nuclei are pushed aside and appear more prominent, and e whole tissue becomes swollen and looser in texture A rious feature of thiosinamine is that its action is only erted on pathological fibrous tissue The objections to its e are its instability, its insolubility, and the extreme itation caused by the injection of its alcoholic solution lix Mendel[2] of Essen, however, discovered that by the mbination of two molecules of thiosinamine with one of licylate of soda a substance was produced which was easily luble in water, was comparatively stable, and did not give e to any irritation on the injection of its aqueous solution this substance—which retained all the properties of iosinamine—was given the name of "fibrolysin"

I first saw the beneficial results obtained by its use some ree years ago in two cases The first was one of upuytren's contraction of the fingers, in which a fair, ough not very good, result was obtained The injections ere given about once a fortnight, the fingers were frequently oved, and the hand was placed on a straight splint in the tervals, the result would in all probability have been much etter had the injections been given twice a week instead of ice a fortnight The second was a case of Volkmann's con acture (the so called ischaemic paralysis), in which a very ccellent result was obtained after frequent injections hese results led me to think that fibrolysin might prove a ery valuable therapeutic agent in the treatment of aural ases, and particularly in those where, as a result of suppura on or catarrh, a development of fibro cicatricial tissue had ken place in any portion of the conducting apparatus of e ear

In my first series of cases the results were not generally tisfactory, some cases certainly showed fair improvement, ut the greater majority were in no way benefited At is time I had been giving the injections once a fortnight, nd I determined to increase them to twice a week and at e same time to apply it locally to the middle ear through n Eustachian catheter—a method employed with success by André Horeau in connexion with thiosinamine The results immediately improved The method which I employ is to use one ampulla of fibrolysin containing 2 3 cubic centimetres—roughly 40 minims—as follows 30 minims are injected subcutaneously into the upper arm, and 5 minims are insufflated through an Eustachian catheter into each middle ear After an interval of 15 minutes massage is applied on each side for from three to five minutes by means of an oto masseur This routine is gone through twice a week for six weeks, if at the end of that time there is no definite improvement my experience is that the case is a hopeless one, and that it is useless to persevere with the treatment

The cases in which I have systematically carried out this treatment are those of deafness and tinnitus resulting from (1) post suppurative middle ear catarrh, where there has been a cessation of discharge with formation of scar tissue and destruction or ankylosis of the ossicles, and (2) chronic dry middle ear catarrh—i e, non suppurative catarrh—retracted membranes, with or without ankylosis of the ossicles

The number of cases that have had the six weeks' treatment have been 68 Of these, 21 were cases of post-suppurative middle ear catarrh and 47 were cases of chronic dry middle ear catarrh Of the 21 cases of post suppurative middle ear catarrh, 16 had tinnitus and five had no tinnitus. Of the 16 with tinnitus, four were complete failures, there was no improvement in hearing or diminution in the noises —indeed, one patient stated that she was much worse in both respects Six had no improvement in hearing, but stated that the noises were less, two of these stated that the noises had completely ceased, and they thought they could hear a little better (this, however, was not borne out by the tests) Six showed good improvement in hearing to the tests, and stated that the noises were diminished in three, completely ceased in two, and no better in one Of the five cases with deafness but with no tinnitus, two showed no improvement and three showed improvement Of the 47 cases of dry middle ear catarrh, 36 had tinnitus and 11 had no tinnitus Of the 36 with tinnitus, 11 were complete failures, eight showed no improvement in hearing to the tests, but stated the noises to be diminished (completely ceased in two), and 17 showed improvement in hearing to the tests, and of these, six stated that there was no diminution in the noises (though in one they had become intermittent instead of being constant), eight stated the noises to be diminished, and three reported the noises to have quite ceased Of the 11 without tinnitus, seven showed improvement to the tests and four showed no improvement

In order to prove that it was the fibrolysin and not the Eustachian catheter and the oto masseur which brought about the improvement, 15 of the above cases—all with tinnitus as well as deafness—were first treated by the catheter and massage for six weeks without having any fibrolysin, and their tests taken, they were then put on the fibrolysin course, and at the end of the six weeks of fibrolysin treatment their tests were again taken and the three sets of tests were compared It was found that in seven out of the 15 there was no improvement in hearing, though two out of these seven reported diminution in the tinnitus The accompanying table shows the improvement in the eight cases which received benefit—three of post suppurative middle ear catarrh and five of chronic dry middle ear catarrh

It will be seen that in Cases 1 and 5 there was a slight improvement in both ears after the six weeks' catheterisation and oto massage, but a very much greater improvement took place under fibrolysin It will also be noticed that the post-suppurative cases gave more consistently good results—i e, greater improvement—than did the chronic dry catarrhs, moreover, in all the above, with two exceptions, the tinnitus was improved and in one it had quite ceased

I turn next to the question of the permanency of the results obtained Of the 16 cases showing improvement in hearing and diminution in tinnitus, ten were treated a year ago or over and have had no treatment since, four were cases of post suppurative middle ear catarrh Of these one only has had a relapse in both hearing and tinnitus, in two the improvement in hearing is maintained, but the noises slightly returned, and in one the improvement in hearing is maintained and there has been no return of the tinnitus Six were [illegible] Of these two have relapsed [illegible] other has [illegible] nution in

Table giving the Results of Eight Cases after Treatment.

Number of case and nature of disease.	Tests applied and results.		Results after six weeks' treatment with Eustachian catheter and otomasseur.	Results after six weeks' treatment with fibrolysin.
Case 1. Double non-suppurative dry middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -16 L. -15	- 11 - 14	- 4 - 6
	T. F. C^{1} 256 Mastoid	R. + 7 L. +10	+ 7 + 9	+ 3 + 4
	T. F. C^{1} 256 Rinné	R. - 7 L -10	- 8 - 9	- 3 - 5
	Watch	R., 6 in. L., 4 ,,	6½ in. 4½ ,,	9 in. 7 ,,
	Whisper	R., 3 ft. L., 2 ,,	3½ ft. 2½ ,,	5 ft. 4 ,,
	Tinnitus.—A loud constant "buzzing" in both ears.		Slightly diminished in both ears.	Noises now intermittent and much diminished in intensity in both ears.
Case 2. Double post-suppurative middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -16 L. -19	- 16 - 20	- 9 - 10
	T. F. C^{1} 256 Mastoid	R. +10 L. +12	+ 11 + 12	+ 4 + 6
	T. F. C^{1} 256 Rinné	R. -11 L. -12	- 10 - 12	- 8 - 8
	Watch	R., 2½ in. L, 2 ,,	2½ in. 1½ ,,	5½ in. 5 ,,
	Whisper	R., 1 ft. L., 8 in.	1 ft. 6 in.	3 ft. 2 ,,
	Tinnitus.—Constant "ringing" in both ears.		No improvement.	Much diminished.
Case 3. Double non-suppurative dry middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -20 L -14	- 20 - 12	- 10 - 8
	T. F. C^{1} 256 Mastoid	R. +10 L. + 8	+ 8 + 8	+ 4 + 6
	T. F. C^{1} 256 Rinné	R. -11 L. - 6	- 10 - 6	- 6 - 5
	Watch	R., 2 in. L., 3 ,,	2 in. 3½ ,,	6 in. 4 ,,
	Whisper	R., 1½ ft. L., 2½ ,,	2 ft. 2 ,,	4 ft. 3 ,,
	Tinnitus.—Constant "buzzing" in both ears.		No improvement.	"Thinks noises are much better."
Case 4. Double post-suppurative middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -14 L. -10	- 15 - 8	- 8 - 5
	T. F. C^{1} 256 Mastoid	R. +10 L. + 6	+ 11 + 5	+ 3 + 2
	T. F. C^{1} 256 Rinné	R. - 8 L. - 5	- 9 - 5	- 4 - 2
	Watch	R., 4½ in. L., 6 ,,	4 in. 7 ,,	10½ in. 24 ,,
	Whisper	R., 3 ft. L., 4 ,,	3 ft. 5 ,,	6 ft. 10 ,,
	Tinnitus.—Constant loud "hissing" in both ears.		Slightly diminished.	States that he very rarely has any noises now.
Case 5. Double post-suppurative middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -26 L. -16	- 24 - 15	- 8 - 6
	T. F. C^{1} 256 Mastoid	R. +14 L. +12	+ 14 + 11	+ 6 + 4
	T. F. C^{1} 256 Rinné	R. -14 L. - 8	- 13 - 8	- 7 - 4
	Watch	R., 2 in. L., 3 ,,	2 in. 3½ ,,	12½ in. 18 ,,
	Whisper	R., 1 ft. L, 2 ,,	16 ,, 2½ ft.	3 ft. 5 ,,
	Tinnitus.—Constant "roaring" in both ears.		Slightly diminished.	Noises markedly diminished and intermittent in left ear. Much diminished but constant in right ear.
Case 6. Double non-suppurative middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -20 L. -34	- 20 - 31	- 8 - 16
	T. F. C^{1} 256 Mastoid	R. +14 L. +18	+ 12 + 16	+ 6 + 12
	T. F. C^{1} 256 Rinné	R. -12 L. -17	- 12 - 16	- 5 - 9
	Watch	R., 1 in. L, 0	1½ in. 0	10 in. 2 ,,
	Whisper	R., 1 ft. L., 8 in.	1 ft. 10 in.	4 ft. 1½ ,,
	Tinnitus.—Loud, constant "buzzing" in both ears.		Same.	States noises a[illegible] not so loud as formerly.
Case 7. Double non-suppurative middle-ear catarrh.	*T. F.* C^{1} 256 Meatus	R. -25 L. -28	- 26 - 24	- 14 - 12
	T. F. C^{1} 256 Mastoid	R. +14 L. +16	+ 14 + 15	+ 10 + 8
	T. F. C^{1} 256 Rinné	R. -10 L. -12	- 10 - 11	- 8 - 7
	Watch	R., C. L., C.	C. ½ in.	2 in. 4½ ,,
	Whisper	R., 1½ ft. L., 1 ,,	2 ft. 1½ ,,	2½ ft. 3 ,,
	Tinnitus.—Loud, constant "ringing" in both ears.		Same.	No improvement.
Case 8. Double non-suppurative middle-ear catarrh.	*T. F.* C_1. Meatus	R. -10 L. -18	- 10 - 19	- 8 - 10
	T. F. C_1. Mastoid	R. + 6 L. +12	+ 6 + 13	+ 4 + 6
	T. F. C_1. Rinné	R. - 7 L. -11.	- 7 - 12	- 5 - 7
	Watch	R., 2 in. L., ½ ,,	2½ in. ½ ,,	4 in. 3 ,,
	Whisper	R., 2 ft. L., 14 in.	2½ ft. 1 ,,	4 ft. 2 ,,
	Tinnitus.—Constant loud "buzzing" in both ears, especially marked in left ear.		Same.	No improvement.

T. F. = tuning-fork. C. = contact. R. = right. L. = left.

the hearing power); four have retained their improvement in hearing, but in two of these there has been in one in whom the noises had quite disappeared an occasional return of the tinnitus, and in the other in whom the noises had considerably diminished there has been a slight increase. Two have retained their improvement in both respects.

Conclusions.—To epitomise briefly the results obtained it will be seen that of the 52 cases of deafness *plus* tinnitus the hearing improved and noises diminished in 16 (noises quite ceased in five of these); hearing improved, but noises not diminished in seven; noises diminished, but no improvement in hearing in 14 (in four of these the noises have quite ceased), and no improvement in hearing and no diminution of noises in 15. In the 16 cases of deafness without tinnitus, ten showed improvement to the various tests.

From the results obtained it would appear that this method of treatment was more successful in the non-suppurative than in the post-suppurative cases; but whilst this was so in regard to the percentage of cases showing improvement in hearing and diminution in tinnitus, yet when taken from the point of view of the amount of improvement produced the post-suppurative cases gave far better results; and I arrived at the conclusion that the fibrolysin treatment is by far the best treatment in this class of case—the earlier the case is treated after cessation of the discharge and formation of the scar tissue the better the prognosis. I think that from the results obtained it will be seen that in cases of non-suppurative middle-ear catarrh this method of treatment gives much better chances of improvement than any other. I must, however, make an exception in the atrophic variety of non-suppurative middle-ear catarrh—the variety in which one finds, on examination with a Siegle's speculum, a very thinned tympanic membrane with an abnormal amount of movement, with marked outward bulging on the application of suction. In this type of case fibrolysin proved quite useless. In true oto-sclerosis the results obtained with fibrolysin were very poor; only two out of 15 showed any improvement, and that very slight.

In only one of my cases were there any bad symptoms produced by the injections. This was a case of a young woman, aged 25 years, with double non-suppurative middle-ear catarrh of two years' duration. She was put on the fibrolysin course, but this had to be stopped owing to her developing marked vertigo after each injection. A number of other cases in which bad symptoms have followed the injections have been reported from time to time,[3] but the above was the only one in my personal experience.

I must, in conclusion, express my thanks to my late clinical assistant at the Great Northern Central Hospital, Dr. Edgar Brown, for having very carefully taken the various tests and kept the records of the cases.

Harley-street, W.

THE FATE OF DAMAGED JOINTS:

A STUDY OF CASES OF INJURY, PRINCIPALLY FRACTURES, INVOLVING JOINTS TREATED IN THE MASSAGE DEPARTMENT OF THE LONDON HOSPITAL.

BY RICHARD WARREN, M.D., M.CH. OXON., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL; FORMERLY SURGICAL REGISTRAR TO THE LONDON HOSPITAL.

(*Concluded from p. 141.*)

The Wrist.

THE most striking feature of this series is the enormous predominance of Colles's fracture; 103 cases out of 110 were of this nature. Taking the remaining seven cases first, these consisted of two cases of sprained wrist, which did well in from two to three weeks (the patients were seen a year or more afterwards); two cases of fracture of the styloid process of the radius, both of which did well in from six to eight weeks. One case of splitting off of a flake of the lower part of the radius, including the lower radio-ulnar articulating surface (this case showed a very fair result a year later); one case of fracture of the styloid process of the ulnar alone (not traced); and one case of fracture of the scaphoid and probably also of the trapezium and trapezoid (this patient attended for five weeks and did not show satisfactory progress when last seen).

Colles's fracture.—Of this group 91 were recent cases of fracture, and 12 were cases of some standing before massage and exercises were commenced. In judging the results the following standard has been used: 1. Very good: Subjectively perfect for any sort of work; in some cases slight deformity was present. 2. Good: Able to do heavy work—e.g., as labourer, cobbler, washing, and wringing, but with a little pain at times and perhaps slight deformity. 3. Very fair: Able to do fairly hard work—e.g., washing but not wringing, i.e., some weakness present. 4. Fair: With a fairly strong grip, and able to do light work—e.g., sewing but not heavy work or washing. 5. Bad: Unable to work at all from swelling, stiffness, and pain.

It will be noted how much the occupations of women came into this list, a natural consequence of the preponderance of middle-aged and old females amongst the subjects of this fracture. Twenty-one cases were not traced, slipping away in the earlier part of treatment. Of the 70 cases traced, the results were as follows: Very good, 12; good, 36; very fair, 7; fair, 9; and bad, 6. In other words, two-thirds of the cases were useful working results, while 1 case in 12 was hopelessly bad.

Age.—Tak[illegible] one of the [illegible] is shown b[illegible] were as follows: Very good, 48; good, 43; very fair, 49; fair, 47; and bad, 59. The subjects of the cases which did badly were on the average ten years older than the other patients. That age, however, is no bar to good recovery is shown by the good results in two cases in which the patients were over 70 years of age, and in eight cases in which they were over the age of 60 years. Under 40 years of age all cases showed good or very good results.

Length of time of fixation.—The time during which the joint is kept fixed before massage and movement are begun is important. Thus of cases kept splinted for less than 14 days before massage, 37 were good and seven were not good—i.e., very fair to bad; of cases kept splinted for from three to six weeks, nine were good and six were not good.

Severity of fracture.—In this series only a quarter of the cases X rayed showed fracture of the styloid process of the ulna; the usual percentage given is about 50. Of nine cases with fractured styloid process of the ulna, seven were good and two were bad—i.e., 1 case in 4 was bad, a higher percentage than is shown by the series as a whole.

Deformity and results.—Gross deformity is apt to be associated with poor result, yet several cases with bad deformity had good working hands and wrists. Of seven cases with bad deformity three were good, one was fair, and three were bad as regards function. As was previously mentioned, the bulk of the cases showed slight deformity, about one-sixth of the cases being perfect anatomically. The results, then, in cases where the styloid process of the ulna is fractured and where deformity is great show the importance of the initial damage in the prognosis.

Duration of treatment.—The time required for treatment varied from about three to 30 weeks, depending on the length of preliminary splinting and fixation and on the age, as the following table shows, for cases in which the results were good or fair.

Number of cases seen.	Weeks treated, average of	Average of fixation in weeks.	Average age.
7	2-4	1	34
12	4-6	1½	44
8	6-8	1¾	53
12	8-12	2⅕	47
9	12-18	3⅓	60
2	18-24	3½	50
2	24-30	4	70

The duration of fixation would seem from these figures to be of more importance than the age of patients in prolonging the time necessary for treatment.

Conclusions about Colles's fracture.—1. The length of time necessary for treatment before function is restored varies with the length of time the joint is fixed on a splint before massage and movements are instituted. 2. Reduction of the fracture is generally possible to some degree, but seldom entirely. 3. Fixation must be very limited both in amount and duration; an anterior cane splint acts well; a posterior splint is inju[illegible] of the wrist an[illegible] no account be [illegible] ht. 4. In cases [illegible] to increase, good results may be obtained without using splints. 5. A splint helps to prevent deformity, though the latter cannot be completely prevented by a splint; and excessive deformity may lead to impaired use of the limb. 6. Deformity, then, although not of prime importance, is best avoided if possible, but stiffness of joints and tendons is a worse evil than deformity. 7. One to two weeks on a splint will generally suffice, but in hospital practice another week may be advisable, as these patients often try to do things with the hand which are too much for the weak state of the wrist and may lead to increased stiffness and deformity. 8. Massage and finger movements should be started on the third day at latest; the wrist can be gently moved at the end of a week. 9. Exercises: In from two to four weeks, according to the state of the wrist, stronger active movements can be indulged in. We find that flexing and extending movements of the wrist combined with gripping are most beneficial; this is accomplished by means of a roller of varying diameter (to suit different ranges of grip) arranged like the roller of a jack-towel, but prevented from rotating too easily by graduated friction at one end. The patient practises rotating the roller against the friction, which is increased as the wrist grows stronger, in both directions. In some cases pronation and supination exercises are also necessary. For active movements a handle can be used, made like the handles of some railway-carriage doors, with a graduated friction resistance to movements of supination and pronation. These movements can, of course, be made best against the resistance of a masseur, but in hospital practice the supply of masseurs is far too small for this purpose, and these simple machines take their place in a very satisfactory way.

---

[3] Karl Grossmann: THE LANCET, Jan. 16th, 1909; and Glas: Wiener Klinische Wochenschrift, No. 10, 1903.

Old Colles's fracture.—Of this condition 12 cases came under observation at periods varying from seven weeks to 24 years after the initial injury. But of these three could not be traced, five did well, and four did badly. Of the five that did well two of the patients were over 50 years of age, the others being young people of from 20 to 30 years of age; the bad cases were all over 56 years of age. In the case of 24 years' standing there were marked osteo-arthritic changes with tremendous lipping of the joint surfaces. Cases which came under treatment after three months did not do well except one of a child aged 11 years, but with children the prognosis is invariably good.

The Elbow.

Injuries about the elbow-joint provide an interesting and varied set of groups of cases. The varieties and numbers were as follows: Dislocations, 9; sprains, 11; osteo-arthritis, 2; fractured olecranon, 18; fractured head and neck of radius, 10; separated lower epiphysis of humerus, 28; separated internal condyle, 13; separated external condyle, 10; separated internal and external condyle, 1; fractured coronoid, 1; T-shaped fracture, 1; and supracondylar fracture, 5—total, 109.

The elbow is one of the joints most frequently involved in fractures. Injury here is essentially a trouble of childhood and adolescence. With the exception of the cases of fracture of the olecranon almost all of the patients were under 20 years of age, injuries in adults being quite uncommon. Taking the individual groups of cases the following are the particulars.

Dislocated elbow.—Dislocation of the ulna and radius backward occurred six times in children of from 10 to 12 years of age and twice in adults. Treatment lasted from five to eight weeks and all the cases did well. One case attended of old dislocation of both elbows in an adult of five months' standing which had been kept in plaster many weeks. Both elbows were very stiff at a right angle and after several months' treatment did not improve at all. This is a good example of the evils of prolonged fixation of joints in adults; I am glad to say the treatment of this case was not commenced in England.

These cases do not need a splint for more than a day or two, a sling and early massage and movement very soon restoring them to their pristine condition. Should there occur fracture of the coronoid with dislocation, and consequent tendency to re-dislocation, the joint would best be placed in acute flexion for from 10 to 14 days.

Sprained elbow.—Of this condition there were 11 cases, three being those of children from five to 14 years of age, and all did well in from four to seven weeks, though often there was extensive stiffness at the outset. It is a question whether these sprains in childhood are not associated with some undiscoverable injury to the epiphyses. In adults the results were not quite so good; two of the men, though doing heavy work as stevedore and locomotive fireman respectively, complained of incomplete extension of the elbow, and in the latter case of inability to throw coal with full power into the fire-box.

Separation of the lower epiphysis of the humerus.—Of this injury 28 cases attended, and 70 per cent. of these patients were under eight years of age; the youngest was two years old and the eldest was 16 years. In 20 cases the results were good, and about half of these were anatomically perfect; the rest were lost sight of too soon to allow satisfactory conclusions to be drawn. In three cases decided cubitus varus was found; in one case cubitus valgus. With regard to the length of time of fixation before massage and movements were applied little difference was noted. When the cases were splinted for from one to three weeks the duration of treatment averaged seven weeks, but in cases splinted for from four to six weeks treatment had to continue on the average for 13 weeks.

Separation of the internal condyle.—The usual age of these patients, of whom there were 13, varied from 12 to 17 years; the youngest was four and a half years of age, and the age of the eldest was 30 years. The results were 10 good and two fair, one of the latter developing symptoms of osteo-arthritis at the age of 16 years. The length of time the patients in this group were splinted before being massaged had little effect on the length of treatment, which varied from six to eight weeks, in one case lasting as long as 13 weeks.

Separation of the external condyle.—Of nine cases seven were of children aged from four to 10 years. In the six cases traced the result was practically good in all; but one case showed excessive callus about the external condyle, with partial dislocation of the head of the radius and impaired power of extension in an otherwise very useful limb.

Fracture of both external and internal condyles.—One case was noted in a man aged 30 years, which was put up in acute flexion, did well in seven weeks, and was perfect a year later.

Supracondylar fractures of the humerus.—Two children aged six years, and three adults aged from 34 to 60 years, form the total of these cases noted. In the cases of the two children the results were good; in the case of the only adult who was traced the result was fair.

T-shaped fracture of the lower end of the humerus.—One patient, aged 17 years, was wired and treated by movement for a month; when seen a year later he had a useful joint with slightly impeded flexion and extension.

Conclusions with regard to injuries of the lower end of the humerus.—Fractures of the lower end of the humerus, which, as will be seen from the above figures, are usually separated epiphyses, do surprisingly well in spite of initial troubles such as excess of callus, great stiffness, and some deformity. Callus melts away after persisting for months in a most gratifying manner, and in very few cases does one find a great mass of it a year or more afterwards. Gross callus was only noted in two of the cases mentioned here, and both were fractures of the external condyle. Stiffness is overcome by persistent massage and exercises, flexing and extending the forearm against a pulley-weight resistance. Deformity in cases of injury to the lower end of the humerus occurs in four directions—viz., limited flexion, limited extension, cubitus varus or outward kinking of the elbow, and cubitus valgus or kinking inward of the elbow. The first condition, that of diminished flexion, is the most important, and when severe is due to a slipping and rotation backward of the lower fragment of the humerus, so that the ulna can flex completely on the lower fragment without being flexed on the humerus as a whole to anything like the proper extent. This indicates the necessity of flexion in putting up fractures of the lower end of the humerus. When in doubt as to the exact position of the lower fragment flexion of the elbow should be as acute as possible, without causing pressure on the soft parts, which tend to swell. Flexion can be made with safety, perhaps, only to a right angle at first, but by degrees in a few days flexion can be made more acute. Again, when passive movements are commenced—say in from seven to ten days—flexion and not extension should be the early movement.

Incomplete extension of the elbow, though fairly common to a slight extent, is seldom of importance practically; it occurs not only in separation of the epiphyses, but also in sprains and dislocations. It can be overcome by gradually increasing extension movements of the joint, both active and passive; finally, by hanging the body-weight from the arms on the horizontal bar.

The "carrying angle" of the elbow, of which a good deal is made in books, is of slight practical importance. The deviations from the normal, called respectively cubitus varus and cubitus valgus, are seldom great, and unless very great do not interfere with the use of the arm. Cubitus varus is the more common of these two deformities and was found in three out of 28 cases, but in each case, although the elbow appeared awkward and unsightly, the function was good. It is only exceptional movements that are affected by this condition —for instance, striking out a rapid straight blow in boxing or in stoking, or pitching coal with a hard straight-forward thrust.

Valgus is less common—one case was found in 28—and has little immediate effect on the use of the limb. The importance of this condition is that in after years occasionally pressure on the ulnar nerve is produced with pain and paralysis.

Treatment of injuries to the lower end of the humerus.—In most of the cases of this series the elbow was kept fixed at a right angle, best with a posterior gutter-splint. Acute flexion is a safer method when X rays are not at hand to ascertain the exact position of the fragments in order that there may be no risk of rotation backward of the lower fragment and consequently incomplete flexion, but with acute flexion the after-treatment is slightly longer—viz., nine weeks instead of seven on the average.

In these cases the elbow may be moved with safety in a week in the direction of flexion, and pronation and supination movements can be made. There is little harm, however, in leaving the joints of young persons fixed for three weeks. As regards the amount of callus, I have never been able to convince myself that early movement increases callus; on the contrary, some of the cases with the greatest mass of callus had been fixed for several weeks without movement.

Operation is hardly ever required for separation of epiphysis in this region, for in these small patients the parts have a much greater power of repair and adapt themselves much better to circumstances than is the case with adults, in whom comparatively slight displacement is apt to be followed by osteo-arthritis due to a different manner of wear-and-tear of the joint, and in whom, therefore, it is much more important to get accurate apposition of fragments, and operation will be more often necessary.

That osteo-arthritis can develop in the young, is shown by one case of a lad, aged 16 years, whose elbow after a fracture of the external condyle showed well-marked changes of this nature.

Further, in children bone, particularly recently formed bone, can be bent to a considerable degree by muscular efforts continued over a long period of time. It is well known how, after excision of the knee, the hamstrings produce gradual flexion of the originally straight knee, unless a rigid support be applied, a flexion going on for years, although the bone is solid and firmly united; similarly in displacements of epiphyses, by constant exercises the fragments, although united, are pulled in the right direction. Thus a great improvement in shape and function can be attained, and hence the value of continued and carefully arranged exercises in cases where there is deformity. Gentle active movements may be used early and together with passive movements, and are of greater value in restoring the use of the joint.

Fractured olecranon.—There were 18 cases, of which four were wired by open operation. The cases traced showed 12 good and one fair result. The duration of treatment averaged from eight to 10 weeks, whether the cases were operated on or not. The cases not treated by operation were such as had very little or no separation except one, which gave a fair result with one inch separation. Separation of the fragments depends largely on the position of the fracture; when near the tip of the olecranon there is much more likelihood of wide separation than when the fracture is nearer the base.

Cases of fractured olecranon with obvious separation are best wired, though fibrous union and considerable separation may coexist with a very useful elbow.

Cases with little or no displacement can be slung slightly flexed and massaged and moved from the outset. Care must be taken when applying a straight splint for this injury to people of middle age, for the constriction of the splint and bandage together with the dependent position of the hand are apt to be followed by a long-lasting œdema and stiffness of the hand and wrist, which is far more crippling than fibrous union of the olecranon. In brief, if the arm will not admit of flexion to nearly a right angle without much displacement of the fragments operation is the best resource.

Fractured coronoid process.—One case of this injury occurred in a lad, aged 17 years, and was perfect in three months.

Fractures of the upper end of the radius.—In this group are cases where the head of the radius was broken in one or more places or more usually in which the head was broken off the neck, in which case it was usually a separation of the epiphysis. Ten cases of this nature were seen, of which eight were those of children of from seven to 13 years of age, while two patients were men of about the age of 30 years. In seven cases the neck was fractured or the epiphysis of the head was separated and in three the head was fractured. The cases in children were all of good results; those of the men, in which the head itself was fractured, were of only fair results, flexion being limited in one case and extension in the other. Treatment averaged from seven to ten weeks, in one case being as long as 20 weeks.

These cases require nothing but a sling and massage from the start, splinting is here of no avail. If stiffness supervenes, excision of the head of the radius may be performed; after this operation, and also in excision of the head for old-standing dislocation of the radius, there is a tendency for supination to be limited; my impression is that enough bone is not removed and should advise in these cases the removal of as much of the neck as is possible without interfering with the biceps tendon.

The Shoulder.

In this series are included contusions, dislocations, fracture dislocations, fractures of the anatomical and surgical necks, and a few cases of injury to the clavicle, acromion, and great tuberosity.

Dislocations.—There were 25 cases of recent dislocation of the humerus, the ages of the patients varying from 20 to 70 years. In four of them there was severe damage to the brachial plexus or some of its cords. The results were: ten good, five fair, one bad, and nine not traced. Of the cases with nerve injury one was very fair, one was bad, and two left off treatment in three months and were not traced. Treatment as a rule lasted from four to eight weeks. It was very noticeable how prolonged fixing of the shoulder necessitated longer after-treatment; two cases in which the arm was fixed for one month to the side requiring 20 weeks and more of exercises and movements before useful function was restored. The last movement to recover, and the one to remain impaired in those cases which did not perfectly recover, is that of the deltoid. This is due, perhaps, in some cases to slight injury to the fifth cervical nerve trunk; more usually I suspect to keeping the arm overlong at the side and so overstretching the deltoid.

Old dislocations.—There were five cases. One case, not seen until four weeks after reduction of the dislocation, did perfectly. Of three cases not seen for three months after reduction one did well, but the patient was only 22 years of age; the other two, aged 63 and 69 years respectively, were fair results; but the remaining case, in which treatment did not commence for a year after the injury, did not improve at all. These cases required longer for treatment than recent cases—viz., about three months.

Recurrent dislocations.—Three cases. One patient, an epileptic, in whom the right shoulder had been dislocated six times and the left 30 times, did not attend long enough to afford any useful information. Of the other cases, one patient had experienced dislocation six times in six months, the other nine times in 12 months. After a few weeks' treatment the latter was found six months later not to have been re-dislocated, while the former was in good order 18 months later.

Treatment.—In the treatment of dislocated shoulders, after reduction it is most important to find out whether there be any nerve injury, a not uncommon complication, as is shown by the cases quoted above; for whatever is to be the outcome of operations on nerves, freeing, anastomosing, splicing, &c., and at present it is far too early to dogmatise on the results of operations which may take years to be fully developed, it is as well to know at the outset whether any nerve be injured, both in order that it may not later be attributed to bandaging, &c., and that when present its consequences may not be aggravated by treatment.

Except in epileptics or patients recovering from an anæsthetic there is no necessity for bandaging the arm to the side; a sling will be quite sufficient, as a considerable amount of abduction of the arm is necessary to produce re-dislocation. Massage should be used from the beginning, for the movement can be started in from two to three days as a rule, and sho
—i.e., flexio
the latter to
beyond 45° from the perpendicular should be avoided for several weeks, since this is the position likely to produce dislocation—these movements should be active as well as passive; later, circumduction should be practised. A very useful and simple machine for practising active movements consists of a large wheel three feet in diameter, with the axis horizontal and about the height of the shoulder; the handle which turns the wheel is so arranged that the distance from the centre of rotation can be diminished or increased; by turning this wheel movements of circumduction of the shoulder of increasing amplitude are

performed. Later exercising with the pulley weight machine to strengthen the deltoid and triceps is made use of, and finally hanging by the arms to get extension over the head, which is the function of the shoulder most difficult to restore.

It is sufficiently clear from the cases mentioned that early movement means early cure, that delayed movement means lengthy cure or perhaps permanent disability, and that recurrent cases are improved by the restoration of muscular tone with regular exercises.

Fracture dislocation.—Four cases of this injury attended: in two of them the head of the humerus had been excised. Of the latter cases, one, a youth, had an arm which was useful for underhand movements; he could swim well side-stroke, but abduction beyond 45° was impossible. In the other, a middle-aged person, the arm was of little use. The other two cases treated by fixation for a short time and then movement and massage did fairly well, getting abduction to the horizontal or more and good power in the arm. These cases bear out the conclusions of Scudder and Mason from the study of a number of cases of this nature—viz., that operation with replacement of the head of the humerus *in situ* is satisfactory, but that excision of the head gives poor results as a rule, and that the more head and neck that has to be removed the less the working capacity of the limb.

Contused shoulder.—In all the five cases of this nature treated there was great weakness of the deltoid, and in two of the cases there was undoubtedly injury to the fifth cervical root. A point of interest is as to whether most of these cases do not owe their chronicity in great part to some injury of the upper part of the brachial plexus. In all these cases treatment had to be prolonged, lasting from three to six months. In two cases the results were good, in two fair; in one of the latter, although the deltoid was atrophic, the patient could abduct the arm well above the head, apparently by a combination of the biceps and pectoralis major.

Fractures of the surgical neck of the humerus.—Of 14 cases, seven were good, five fair, and one bad, and one was not traced; 60 per cent. of the patients were over 50 years of age. The bad result was associated with and largely due to an injury of the brachial plexus. The length of treatment was from seven to ten weeks.

Fractures of the anatomical neck.—Three cases, the patients all being well over 60 years of age. Two did very well and one was a fair result. The length of treatment was about the same as in fracture of the surgical neck.

Fracture of the great tuberosity.—One case occurred with weakness of the deltoid, possibly due to injury of the fifth cervical root; this case did well after 20 weeks' treatment.

In all these fractures of the upper end of the humerus there is a tendency to keep the shoulder fixed too long before massage and movements are commenced. Fractures in this position unite very readily and in 14 days a good deal of movement can be indulged in without risk of displacement. Such cases should be massaged from the earliest possible time and movement can probably be started in from 7 to 10 days. Keeping the shoulder fixed for a month is far too long. As in the other injuries of the shoulder, weakness of the deltoid is the main and most lasting trouble here.

Fractured clavicle.—Two cases of trouble after fractured clavicle attended, and required from six and eight months respectively before they were in a satisfactory condition. It may not be out of place to give a word of warning about the putting up of fractured clavicles. Too much attention is apt to be paid to getting a very good position of the fragments, with consequent tight application of strapping in the manner of Sayre, which is apt in patients of middle age and upwards to be followed by certain unfortunate results. I will mention three: 1. The hand is kept extended and strapped to the chest and after three weeks resembles a whale's flipper, a condition likely in the elderly to persist indefinitely. 2. Pressure of strapping on the arm affects the nerve- and blood-supply of the forearm, causing œdema, a certain amount of nerve palsy, and, I suspect, a varying slight degree of ischæmic degeneration of muscle, which adds to the rigidity of the hand. 3. Fixing the shoulder often results in prolonged stiffness. A concurrence of these conditions causes the limb to be of neither use nor beauty, and very likely the fragments of the clavicle are still displaced. The digits of the middle-aged should never be fixed when fixation can possibly be avoided. The shoulder in such people should be treated with respect and not restricted for long, but the hand even more so, for a stiff and flipper-like hand is a worse affliction than a stiff shoulder; in putting up a fractured clavicle in the middle-aged, the hand should be left out of the strapping. If it be deemed necessary to get a very good position of the fragments of the clavicle it will be better to cut down and wire; this method is, however, not likely to come much into vogue, for a clavicle which is an abomination to the æsthetic eye of the surgeon may yet be of the greatest service to its owner, provided that there is a useful hand at the end of the limb.

Conclusion.

On the whole, the results quoted are not bad, though certainly admitting of considerable improvement. If modern treatment be carried out, the outlook of fractures involving joints is less gloomy than some would have us believe. Unless cases are made to come and show themselves after treatment has ceased, one gets a false perspective of the results; one sees cases coming up week after week and month after month with very little signs of improvement. Two or three cases of this nature certainly give one the impression that no case, say, of Pott's fracture, ever did or ever will recover the use of his leg, and one is surprised later to find how many of the cases are quite respectable working results. Cases doing well slip away, their treatment is shorter, and they leave less impression on the mind than do those stiff, squab, œdematous, and utterly dreadful-looking ankles which are our constant visitors. With patience and perseverance, however, these latter assume something of their normal proportions and are, at any rate in the majority of cases, exceeding useful and serviceable means of progression. I have found to my surprise the after-result much better than I expected. From the cases discussed the value of early movement and massage will be readily seen in improving and accelerating recovery of function. Massage and movement alone are not suitable for all fractures, though serviceable for a great many more than is commonly supposed. Certain fractures—e.g., Pott's fracture—must have some retentive apparatus to avoid displacement, not to produce immobility of the limb.

In the treatment of fractures and allied injuries, as in a very large number of medical and surgical cases, two great and apparently opposing principles are used—viz., rest and exercise. In the past too much stress has been laid on the importance of rest in cases of injury, and it is largely to the French school that the credit is due of accentuating the importance of the other great factors in treatment, movement and exercise. For movement leads to power of function, and it is by a proper appreciation of the importance of each of these principles and by correlating their application in practice that we shall obtain at length such perfection as is possible in this world of mortal men.

Finsbury-square, E.C.

THE LONDON HOSPITAL MEDICAL COLLEGE.—On July 19th the prizes and certificates were distributed to the successful candidates of the Medical College of the London Hospital. The distribution was made by the Earl of Derby, the treasurer of the hospital. The list of the scholarships and prizes awarded included the following:—Price entrance science scholarship: Mr. D. E. Morley. Price entrance scholarship in anatomy and physiology: Mr. J. Scott Wilson. Entrance science scholarships: Mr. J. R. K. Thompson and Mr. A. R. Elliott. Buxton scholarships in arts: Mr. G. Bluett and Mr. A. P. Ford. Epsom scholarship for students of Epsom College: Mr. K. Biggs. Scholarship in clinical surgery: Mr. A. H. Penistan. Scholarship in clinical medicine: Mr. W. J. O'Donovan. Scholarship in clinical obstetrics: Mr. G. Gushue-Taylor. Duckworth Nelson prize: Mr. A. H. Penistan. Senior Letheby prize in organic chemistry: Mr. J. R. K. Thompson. Senior Letheby prize in inorganic chemistry: Mr. E. Morley and Mr. D. E. Morley. Junior Letheby prize in chemistry and physics: Mr. T. H. Thomas. Sutton scholarship: Mr. A. H. Penistan. Anatomy and physiology scholarship: Mr. T. D. Williams. Anatomy and biology scholarship: Mr. T. D. Williams. Minor surgery prizes: Mr. H. B. Walker, Mr. F. Sanders, Mr. B. R. Khanna, Mr. G. M. Heiron, Mr. W. Morris, and Mr. D. Scott. *Practical anatomy prizes*: Mr. R. G. Brown, Mr. J. V. O. Andrew, and Mr. N. L. Treston. Anderson prizes: Mr. J. S. Jobson, Mr. F Sanders, Mr. H. R. G. Vander Boken, Mr. J. G. Reidy, Mr D. Scott, and Mr. R. E. Quinton. Douro Hoare prize: Mr. H. W. Parrott. Wynne Baxter prize: Mr. E. B. Morley.

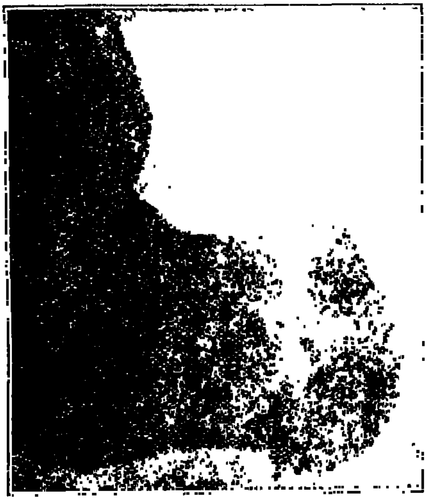
"PAINFUL HEELS.'

BY E. REGINALD MORTON, M.D. TOR., F.R.C.S. EDIN.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, LONDON HOSPITAL; LECTURER ON RADIOLOGY, WEST LONDON POST-GRADUATE COLLEGE.

THE annotation entitled "Painful Heels" in THE LANCET of June 12th (p. 1704) has encouraged me to record the following case, which throws some light on a subject which has, so far, been very little written about. The lady in question was brought to me by Dr. H. Beckett-Overy, to whom I am obliged for permission to publish the following details:—

The patient, aged 60 years, was first seen on April 26th last with a history of pain and tenderness in the right foot and heel, which had got progressively worse during the past four months. At a later date the left foot and heel began to give trouble in the same way. Latterly the pain in the feet had been severe and the tenderness on pressure in each heel had steadily increased. Walking was attended by extreme discomfort, so that she had been unable of late to take any exercise. There was a distinct gouty tendency, but nothing else of a constitutional character. The patient was sent to me in the hope that some form of ionic medication would be helpful, as she was anxious to avoid an operation if at all possible.

FIG. 1.

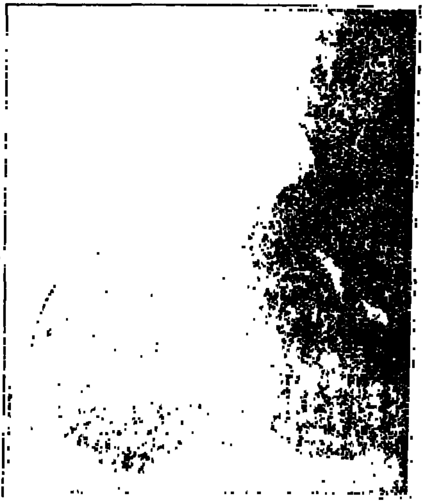


From a skiagram of the right foot.

The case being an unusual one and the diagnosis not at all clear, I suggested that I should make a radiograph of each heel, which I did with the result as shown herewith. (See Figs. 1 and 2.) It will be seen how the development of the thorn-like process, projecting forwards, is more complete on the right side than on the left, and thus exactly conforms to the clinical history. There will also be noticed the thickening of the tubercle of the os calcis, an extra layer of bone being deposited thereon.

Steinhardt considers that gonorrhœa is one of the most common causes, and that males are more often affected than females. Only a few days ago I was informed by a New York surgeon that at least one of his colleagues looked upon these spicules of bone growing from the os calcis as pathognomonic of gonorrhœal infection. Steinhardt, however, admits the possibility at least of the condition being due to gout, rheumatism, and traumatism. The present case was clearly not gonorrhœal.

FIG. 2.



From a skiagram of the left foot.

Ionisation, first with salicylic and later with iodine ions, was tried for a brief period, but, as might have been expected, the result was negative.

I understand that on May 29th the spicules were removed [illegible] the amount of benefit obtained is [illegible] signs of general improvement. [illegible] to walk.

Upper Wimpole-street, W.

PURPURA HÆMORRHAGICA, WITH ABDOMINAL CRISES DUE TO INTESTINAL EFFUSION.

BY G. PERCIVAL MILLS, M.B., B.S. LOND., F.R.C.S. ENG.,
LATE RESIDENT SURGICAL OFFICER, SALFORD ROYAL HOSPITAL.

ON March 21st, 1909, the patient, aged 16 years, was sent to the Salford Royal Hospital by his medical attendant, and complained of severe abdominal pain. The family history was excellent; no tuberculosis or rheumatism. The patient had suffered occasionally from "growing pains." With this exception he had had no previous illnesses. He had never suffered from rheumatism or sore-throat. Ten days previously he had been seized while at work with pain in the lower part of the abdomen. The onset was gradual and at first the pain was only severe when he attempted to lift anything. He vomited once and the pain got so severe that he had to return home and go to bed. The pain was not relieved by rest but came on in frequent paroxysms which were severe enough to necessitate the administration of morphia. He localised the site of the pain vaguely to the lower half of the abdomen and described the attacks as resembling colic. He remained in bed on a fluid diet for ten days, during which no improvement took place.

On admission the patient was seen to be a fairly well-built boy. The expression was pinched and anxious, the tongue dry and brown, and both it and the lips and teeth were covered with sordes. The abdomen was soft and moved freely on respiration. There was slight tenderness on deep palpation in the right iliac fossa, but otherwise examination revealed nothing abnormal. Per rectum nothing abnormal was felt. The temperature was 98·4° F., and the pulse was 80 and of fair volume and force. An aperient was given and the bowels were freely opened three times. The stools were fluid and of normal colour, but contained a trace of blood intimately mixed and a little mucus. Examination of the urine showed nothing abnormal. The patient continued to have attacks of the most violent abdominal pain, rolling about the bed in agony, and his general appearance was one of extreme illness. A provisional diagnosis of chronic intussusception was made.

Operation.—With the consent of Mr. Andrew Boutflower, who kindly allowed me to treat the case, I opened the abdomen through the right rectus muscle on March 23rd. There was a little clear fluid in the peritoneal cavity, and the parietal peritoneum was slightly hyperæmic. Along the whole length of the small intestine there were numerous patches of hyperæmia and œdema. The lowest was a few inches above the ileo-cæcal valve; it extended all round the intestine and was about two inches in length. The intestinal wall was slightly thickened and markedly œdematous and hyperæmic, but there was no extravasation of blood. There were similar patches at intervals of 9 to 12 inches along the whole length of the small intestine, giving it a curiously striped appearance. They exactly resembled one of the cases described by Dr. G. A. Sutherland in THE LANCET of June 26th, except that they did not all extend round the whole circumference of the intestine. About two feet from the duodenum there was a circular scar causing a very slight constriction. It was obviously old and resembled the scar of an old intussusception. There was no deposit of lymph or any other sign of inflammation, old or recent. The vermiform appendix and large intestine were normal. The abdomen was closed in the usual way. On the following day (March 24th) there was only one slight attack of pain and on the next day there was no pain. On the 26th there appeared a few typical purpuric spots on the left wrist. They were grouped together on an area of about one and a half inches by one inch on the ulnar side, and there were no spots anywhere else on the body. Later in the day, however, two small spots appeared on the back of the left hand. On the 27th there were more spots on the back of the left forearm and hand; there was again slight abdominal pain, and blood was present in the stools to the same extent as before. On the 29th spots appeared on both elbows and ankles; the temperature remained subnormal throughout except during the formation of a stitch abscess. On the 30th there was a thick cloud of albumin in the urine; no blood or casts. The total quantity was 36 ounces; general condition better. On April 11th there was profuse hæmaturia, some free fluid in the peritoneum, while the feet and legs were œdematous. The patient seemed much worse. The œdema persisted until May 7th, and the peritoneal fluid until June 20th. At the present time (July 5th) the patient is convalescent; there is no abdominal pain and the fæces are free from blood. There is still, however, a trace of blood in the urine.

The case is of particular interest in view of the theory of the causation of intussusception put forward by Dr. Sutherland in the case already mentioned. Dr. Sutherland quoted a number of cases in which this condition of intestinal effusion was found during a laparotomy for supposed intussusception, and showed that it had been not unnaturally regarded as the result of an intussusception spontaneously reduced. He brought evidence to show, however, that (*a*) all the symptoms of intussusception may be caused by intestinal effusions, and (*b*) that intestinal effusion itself is a cause of intussusception. My case presents a certain amount of evidence in favour of both these views. Before operation it was regarded as a chronic intussusception, and had only one patch of hyperæmia been found a diagnosis of spontaneous reduction would probably have been made. He would be a bold man, however, who would assume the presence of 12 to 15 intussusceptions, all of which had undergone spontaneous reduction, to account for the condition found. Consequently it must be admitted that intussusception may be closely simulated by multiple patches of intestinal effusion, and, if so, why not by a single patch?

The other point of interest centres in the old scar found; its appearance strongly suggested an old intussusception, and the occurrence of intussusception and of intestinal effusions in the same patient is, to say the least of it, suggestive.

NOTE ON THE TREATMENT BY RADIUM OF LYMPHATIC OBSTRUCTION (CERVICAL, SUBMAXILLARY, AND AXILLARY) IN A PATIENT SUFFERING FROM FILARIA NOCTURNA.

BY A. A. WARDEN, M.D. GLASG. & PARIS,
VISITING PHYSICIAN TO THE HERTFORD BRITISH HOSPITAL, PARIS.
With Comments by DR. H. DOMINICI *and* SIR R. HAVELOCK CHARLES, M.D., *Physician in Ordinary to H.R.H. the Prince of Wales.*

THE remarkable and rapid success that attended the use of radium and the fact that this is perhaps the first occasion that other than surgical measures have been effective in filariasis encourage us to place on record some details of the case. It may be premised that operative removal of the axillary mass had been attempted and abandoned on account of a prolonged syncope under chloroform, and Sir Havelock Charles, consulted by the patient in London, negatived further operative interference.

Authorities are agreed that "no drug destroys the embryos in the blood,"[1] or indeed "has any effect on the worm once it is introduced into the body. For the effects of lymphatic obstruction, elephantiasis, &c., something can be done by careful bandaging and massage, but as a rule surgical operations are necessary if the removal of the deformity is desired."[2] Sir Havelock Charles felt justified, therefore, in recommending a trial of radium and the patient was sent to me for that purpose. During treatment, which lasted six weeks and which in no way interfered with the patient's comfort during the day, his general health improved and he frequently remarked on the pleasantness of Paris as a health resort in spring!

Past history.—The patient, aged 45 years, in a stay of 22 years in India had spent nine in the temperate climate of the hills in the hot weather, the rest in Bengal proper. In 1885 and 1886 he had a three days' attack of high fever in the Nadia district. In 1895 he had a mild attack of enteric fever, and in July, 1906, he caught 24-hours' fever "by sleeping in the jungle." In June–July, 1907, he had a six weeks' attack of "hill-diarrhœa," contracted at a hill station, Shillong, where such illness was common. The following year at Darjeeling he had a similar illness, lasting about the same length of time.

Present illness.—Early in August, 1908, that is to say, when convalescent from his second attack of hill-diarrhœa, he first noticed a swelling above the left clavicle. It caused no pain and was noticed accidentally by the patient. In October a cough developed which the patient could not shake off, and during the next few months his general health failed considerably, although he continued his arduous administrative duties. Early in January, 1909, a swelling was noticed under the left arm, and the civil surgeon who was consulted at the time recommended his going to Calcutta for operation. There Lieutenant-Colonel H. W. Pilgrim, I.M.S., of the Calcutta General Hospital, found filaria in the specimens of blood taken at night, and in consultation with Major R. Bird, I.M.S., professor of surgery at the Medical College, Calcutta, it was decided to remove the axillary mass. A prolonged syncope under chloroform prevented the completion of the operation, but part of the mass was removed and examined by Major L. Rogers, I.M.S., bacteriologist to the Government. On the patient's return to England early in February he consulted Sir Havelock Charles, who also found filaria nocturna embryos in the blood, and expressed the opinion that the enlargement of the axillary and cervical glands was due to their presence and that further surgical interference was inadvisable. He recommended a trial of radium and the patient arrived in Paris on April 7th and had his first treatment on the 10th.

Present condition.—The patient is some four pounds under his normal weight and still suffers from general malaise, especially in the evening, when the temperature, taken carefully four times daily, shows a regular rise of 1½° F. Physical examination detects no abnormality in the heart, liver, abdomen, lungs, or urine. Under the skin in various parts of the body—e.g., the forearm, abdomen, and back—are small elastic tumours apparently fibro-lipomatous in nature. The patient had noticed some of them as long as 14 years ago.

---

[1] Osler: Principles and Practice of Medicine, fourth edition, p. 362.

[2] C. W. Daniels, Medical Superintendent of the London School of Tropical Medicine, in Hutchison and Collier's Index of Treatment.

The filarial lesions.—These were in four groups: (1) Left axillary; (2) left cervical; (3) submental; and (4) right submaxillary. 1. In the left axilla was a scar 2 inches in length, at the upper part of which a mass could be felt, deep in the axilla, measuring 4 inches by 2 inches and stretching transversely across the line of cicatrix. 2. Above the left clavicle [illegible] 4 or 5 inches in diam [illegible] rder of the trapezius [illegible] nd posterior triangles [illegible] 1½ inches to each side of the middle line, could be felt a firm, elongated, fleshy mass, l [illegible] d consistence. 4. [illegible] of the size of a cherr [illegible] rs were painful and the skin over them was unaltered.

Radium treatment.—The details of the radium treatment are given in Dr. Dominici's note. It entailed no discomfort or pain to the patient, and under its influence the several glandular masses rapidly diminished in size. By the end of May a small tumour measuring 1 inch by ½ inch could be detected in the axilla at the upper extremity of the scar, and of the cervical adenitis one small gland could alone be felt.

As it had been found that the tumours continued to diminish in size when treatment was suspended for a period of ten days, and as the patient was anxious to return to England, it was agreed to postpone further action till later, if necessary. The patient's general health had improved, his temperature had been normal for over a month, and his appearance was that of perfect health.

NOTE BY DR. DOMINICI.

Le malade fut soigné d'après la méthode radiumthérapique dont j'ai, le premier, exposé les principes et démontré les effets dans une série de communications qui remontent [illegible] Paris, 1907.[3] Cette méthode que [illegible] u Rayonnement ultrapénétrant," [illegible] nement du radium au moyen d'écrans de métaux denses (plomb, or ou argent) de 4/10 de mm. à plusieurs mm. d'épaisseur. Utilisés à doses thérapeutiques et avec certaines précautions les rayons qui ont franchi ces écrans métalliques restent capables de déterminer la régression soit de certaines tumeurs, soit de certains processus inflammatoires dont les éléments sont vraisemblablement beaucoup plus sensibles aux rayons filtrés que ceux des *tissus normaux.*

Les adénopathies furent soumises au rayonnement des appareils suivants: 1° Un appareil à sel collé, rond, supportant 5 cg. de sulfate de radium pur; 2° Un appareil quadrilatère de 9 cm.q. contenant 2 cg. 1/2 de sulfate de radium pur; 3° Un appareil constitué par deux toiles quadrilatères de 4 centimètres carrés, supportant chacune 1 cg. de sulfate de radium pur.

Ces appareils furent montés suivant ma méthode, c'est-à-dire en superposant à chacun d'eux : 1° Un écran de plomb dont l'épaisseur fut, en la circonstance, de 2 mm. 2° Un écran de papier de 3 mm. d'épaisseur. Le tout était engainé de caoutchouc. Les appareils ainsi montés fournissaient, à *travers leurs écrans, un rayonnement essentiellement constitué* par des γ et des β ultrapénétrants. L'intensité de ce rayonnement était: Pour l'appareil rond, contenant 5 cg. de sulfate de radium pur, 10,000. Pour l'appareil carré contenant 2 cg. 1/2 de sulfate de radium pur, 6000. Pour l'appareil constitué par les deux toiles à 1 cg. de sulfate de radium pur, 7000. Ces appareils furent situés à peu près indistinctement sur les différentes régions malades, exception faite en ce qui concerne celui formé par les deux toiles et qui fut destiné à la partie la plus élevée du creux axillaire. Grâce à la souplesse relative des toiles et du plomb, on donna à l'appareil une forme concave-convexe de manière à l'adapter, par sa convexité, à la concavité de l'aisselle.

Les applications furent réparties de la façon suivante : Adénopathies sous-maxillaires gauches, 4 applications à gauche, 4 applications à droite; Adénopathies sous-maxillaires droites, 2 applications; Adénopathies de la région cervicale gauche, 6 applications; Adénopathies sus-claviculaires, 5 applications; Creux axillaire, 13 applications, dont 6 à la partie tout à fait supérieure. La durée de chaque application fut de 12 à 14 heures. Afin d'incommoder le moins possible le malade, ces applications eurent lieu généralement pendant la nuit, les appareils restant maintenus au moyen de diachylum. Afin de diminuer le nombre total des séances, on pratiquait les applications d'une façon simultanée dans les différentes zones traitées. Les adénopathies sous-maxillaires, sous-mentionnières, cervicales, et sus-claviculaires disparurent complètement sous l'influence du rayonnement.

Le bloc massif constitué par les adénopathies de la région de l'aisselle se résorba peu à peu, en laissant comme reliquat deux ganglions indurés qui persistent encore à la partie la plus élevée du creux de l'aisselle. Si la tuméfaction de ces ganglions persistait, je conseillerais, pour la réduire, d'introduire pendant 24 heures dans l'épaisseur du tissu conjonctif du creux de l'aisselle un des appareils qui ont été construits suivant mes indications et qui sont constitués par une ampoule de verre cylindrique contenant 5 centigrammes de bromure de radium pur, placée dans un étui d'argent ou d'or à paroi de 5/10 de mm. d'épaisseur. Quoi qu'il en soit, les résultats obtenus sont très intéressants pour plusieurs raisons: les adénopathies échappaient à toute intervention [illegible] de l'observation du Dr. Warden. [illegible] étaient à la fois massives, [illegible] Elles ressortaient d'un agent très spécial, puisque celui-ci était un nématode du type des filaires. Or, si j'ai déterminé l'atténuation ou la disparition, au moyen de la radiumthérapie, d'arthrites blennorrhagiques graves, d'inflammations paramétriales, dont s'entourent les cancers de l'utérus, de syphilomes chroniques, étendus et rebelles au traitement spécifique, des éléphantiasis d'origine streptococique, je n'avais jamais expérimenté l'action du rayonnement du radium contre les réactions inflammatoires provoquées par un parasite du type *des vers.*

En l'espèce, le rayonnement a paru agir non seulement contre les réactions inflammatoires provoquées dans les tissus par la présence des parasites, mais contre ces parasites eux-mêmes, à en juger par la cessation de la fièvre. Si la disparition de l'état fébrile est en relation avec la destruction des nématodes, il y a lieu d'espérer que le champ d'action du radium s'étendra à d'autres parasites de la classe des vers, et qu'il sera possible un jour de traiter par la radium-thérapie combinée à la chirurgie des affections telles que le kyste hydatique, par exemple.

NOTE BY SIR HAVELOCK CHARLES.

The progress of this case (June 24th, 1909) has been highly satisfactory. When first seen by me nothing could be done surgically, and medicine gave no hope. The patient's condition is well described by Dr. Warden, to whom I sent him. I was able in Paris to note the favourable progress made whilst under treatment. I should desire to draw the *attention of those* who have to do with such affections to the beneficent influence of radium in this case. It promises much, and I think there is a great field before it in filarial trouble. Were I again returning to the tropics I should certainly equip myself with a working quantity of this element for use there. Since my lot is differently cast I suggest to others the trial in favourable cases of the radium treatment.

A SURREY CONVALESCENT HOME.—Sir Trevor Lawrence, Bart., presided over the gatherings in connexion with the S [illegible] Home for Men at Seaford, Sussex, he [illegible] The Home was built and [illegible] ander, and was opened in [illegible] lge. The Duke of Teck is [illegible] no fewer than 10,133 patients have passed through the Home, 613 during the year just ended. The financial position of the Home has been well maintained, but extraordinary expenditure during the past year has resulted in a deficit of £87.

DISTRICT MEDICAL OFFICERS AND THE REPORT OF THE ROYAL COMMISSION ON THE POOR-LAWS.[1]

BY MAJOR GREENWOOD, M.D. BRUX., LL.B. LOND., D.P.H.,

HONORARY SECRETARY TO THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

AT the Hull meeting last year I had the honour of reading a paper on the Grievances of District Medical Officers. I referred to the investigation of the Royal Commission then sitting, and stated that most of our grievances had been represented to that body, and I expressed a confident opinion that when its work was completed we should not be forgotten and might hope for an amelioration of many evils that had for long years interfered with the efficiency of our service and the well-being of the State poor. I fear that my confidence in the work of this Commission, in the light of what has happened, was somewhat misplaced, and my hopes for an improvement of our present position more or less premature. We cannot complain that our work in the past has not been recognised, as both in the Majority and Minority Reports there is a fairly ample recognition of our services. On p. 278 (161) we read:—

> Looking to our evidence we are satisfied that the great majority of medical officers efficiently and punctually perform the duties entrusted to them, and that, as we shall show hereafter, many bestow on the poorer classes a considerable amount of attention for which they receive no recompense, &c.

That our complaints have been more than justified is likewise confessed on pp. 268 and 269. But when we look for practical recognition of our long and faithful service what do we find? The proposal of the majority of the Commission is to abolish as soon as possible our office. As members of the class doomed to extinction we can hardly be expected to be delighted with this prospect. But, none the less, we are ready to admit that our service was created for certain public ends, and that if these can be attained better in other ways we have only to submit with the best grace we can.

I think, however, we have a right to express our opinion on what it is proposed to substitute for our services, and to examine and criticise the reasons given by the Commission for so drastic a change. Our present Poor-law system, like the British Constitution, was never created in any cut-and-dried fashion. Both have grown with the needs of the country. Theoretically, no doubt, both might be abolished and re-created with advantage. But in vital matters of this kind it has never been the practice in this country to abolish and root out old institutions in favour of new ideas that may arise from time to time. It has rather been customary to make old institutions fit into new needs and serve for new requirements as they arise by making suitable amendments. Such a method may be slow, but there is an element of sureness and stability about it which is not to be despised, and it is well recognised in the history of civilisation that the most revolutionary changes are not always followed by a maximum of advantage.

In my opinion there is too much of the spirit of destruction in the report before us; too much desire manifested to overthrow and build anew on entirely fresh foundations, regardless of the consequences to other important public interests. For two centuries and more men of eminence and ability have laboured in their generation to construct the present system, and its history has been one of continuous, if slow, advancement. Our Poor-law system a century ago was far worse than now, and if we regard the Poor-law medical service of to-day and compare it with what it was according to the description of writers of even a generation ago, we cannot help being struck by the advancement it has made even in that short period.

Some of the foregoing remarks, in my opinion, might apply to the report as a whole, but as it is only my business to deal with Poor-law medical relief, and more especially with that portion which comes within the scope of the district medical officer, I shall in the rest of my paper restrict myself to that subject only. In the first place, why are district medical officers to be abolished? On pp. 278 and 279 (161) the only qualification to the expressed efficiency of the present district medical officers in the eyes of the Commissioners would seem to be because of the evidence of certain witnesses, that some of the State poor are unwilling to employ them and for the following reasons: (1) That the attention they get from the district medical officer is not satisfactory, and that they frequently call in another doctor; (2) that they will often pay a fee of sixpence or a shilling and travel considerable distances rather than employ the district medical officer; and (3) that it is a great hardship not to be able to choose their own doctor. Surely such reasoning is not conclusive! Does it never happen in ordinary medical practice that a patient becomes dissatisfied with the doctor he himself has chosen and calls in another? Where is there any evidence to show that the change of doctors is more common in Poor-law than in other medical practice? Even if it is admitted that there is more likelihood of such a change where the patient has not chosen his doctor, I have no hesitation in saying that a much more frequent change of doctors takes place in the case of contract practice, including in that category Post-Office and other public services, than in Poor-law practice, and it is with contract practice that that of the Poor-law ought to be compared. Yet no one has proposed to abolish contract practice.

With regard to a preference shown by some of the State poor to pay for their medical attendance, this need not detract anything from the efficiency of the district medical officer. Surely, it is right that poor persons should pay, where they can, for their medical wants, and that they should be encouraged to. The suggestion in the Report is that the poor do so because the district medical officer neglects them, but this is not proved—the finding of the Commissioners is all the other way. I consider the calling in of another doctor more often the result of a feeling of independence on the part of the patient, an independence that should be fostered and not discouraged, as I fear may easily be done by some of the proposals of the Commissioners. There is, perhaps, one other consideration that ought to be mentioned, and that a sentimental one but deeply rooted in human nature—viz., the idea that an article is worth just what you pay for it, and where nothing is paid its value is not usually counted high. The expression "pay doctor" not infrequently found on the lips of a poor person no doubt has reference to that idea, and I have heard it applied as a distinction between a private and hospital doctor as well as a Poor-law doctor. The same idea is exemplified on p. 870 of the Minority Report, where it is stated that evidence is shown that certain members of clubs in serious illnesses discard their club doctor and call in a private practitioner. No doubt it is a hardship not to be able to choose your medical relief, but not greater than having the choice of your other relief restricted. The real hardship is being in a a position to require either. Abundant reasons are given by the Commissioners themselves in the Minority Report on p. 874, why such objections cannot be sustained. What is urged there against the principle of permitting the State poor their choice of a doctor seems to me trenchant enough and quite conclusive.

There is yet another complaint against the work of the district medical officers generally which must not be overlooked, and it has reference to the kind of treatment they are said to give to the poor. In various parts of the Report it is averred they give no advice to their patients to prevent future illness, that all their efforts are directed to treat the immediate ailments, that they do not regard their sanitary surroundings, and consider their duty ended by visiting and prescribing a medicine. Perhaps this charge is best seen in the Minority Report, p. 851:—

> In too many Unions it is clear outdoor medical relief begins and ends with a bottle of medicine, and in the twentieth century we have ceased to believe in the bottle of medicine.

True, most worthy Commissioners, but are you quite sure that even a considerable portion of the mass of the population throughout the country, for whose welfare you were appointed, hold your views with regard to the "bottle of medicine"? Such criticism, if true, condemns not only Poor-law medical practice but at least nine-tenths of the medical practice of the country. Poor-law medical officers are, in fact, criticised adversely for treating their State patients in the same way that private patients are treated by most of the doctors of the community.

Some years ago I attended a public meeting and heard a well-known hospital physician condemn the exorbitant amount of physic ordered for the out-patients of a large London hospital. The Hon. Sydney Holland was also present and asked, somewhat angrily, why physicians ordered medicines they appeared to think unnecessary. His question I do not think was satisfactorily answered, but I doubt if any experienced medical practitioner was ignorant of the reason—a very sufficient one in my opinion—that the public would have the medicine. The medical practitioner is a servant, if not the slave, of the public, and until his masters are better grounded in the facts of physiology and hygiene, advice given by a doctor, unaccompanied by the inevitable physic, would in many cases only result in the ruin of the doctor. Poor-law medical officers least of all can pose as medical reformers, and if they were to treat their State patients differently from their other patients a storm of indignation would arise from even a twentieth century public.

---

[1] A paper read at the annual meeting of the Poor-law Medical Officers' Association of England and Wales held at the Guildhall, London, on July 6th, 1909.

There is, I think, a great deal of misapprehension in the minds of the Commissioners in their criticism of the treatment meted out to their State patients by district medical officers, and in some material points they fail to realise their position. They must be aware that in all medical practice outside the Poor-law, the notions and prejudices of the patients have to be seriously considered by the doctor. Do they think that in the case of pauper patients this is not the case? No district medical officer could properly attend to his district if he were to ride roughshod over all the erroneous and ignorant ideas of his poor patients, telling them dogmatically what they must do and what they must not do, and sternly refusing to compromise in anything. If the patient refuses to follow the district medical officer's advice the latter must still attend him. In no other class of medical practice is the position of the doctor more difficult. Under the present Poor-law system—and so I believe it must be under any Poor-law system—it is impossible for the district medical officer to get rid of his responsibility. Though the patient insult him and will in no wise follow his advice, if the case is serious he dare not leave it, but must continue in attendance, trying by tact and judgment to do the best he can. If every destitute person who chose to set up his opinion against that of the doctor could be haled off to a Poor-law institution, as to a prison, some of this difficulty might disappear, but I do not think the time has yet come when any Parliament would sanction such a procedure.

On p. 269 of the Majority Report we read:—

> It is alleged that the appointment of district medical officer is valuable to the holder apart altogether from the monetary emoluments attached to the post.

This at times must be true, for otherwise, looking at some of the salaries paid, no one could be found to accept such posts. The statement, no doubt, has reference to the introduction to practice that they afford to the young doctor. But if he is going to build his practice on such an appointment he must be specially attentive to his pauper patients and must humour their whims. He must not be too explicit in pointing out their dirty habits, or urge too vehemently sanitary considerations, often as unintelligible to them as objectionable. If he does, he will reap no advantage from his Poor-law office, but rather tend to lose. For, far from recommending, his pauper patients will warn others against him and where they can will themselves call in a "pay doctor." This action on their part will very likely be misconstrued by local philanthropists and put down to neglect on the part of the parish doctor.

On pp. 871, 873, and 874 the Minority Commissioners eloquently denounce certain evils likely to arise where the pauper is permitted to choose his doctor. The district medical officer desirous of gaining practice through the good offices of his pauper patients could not afford to regard these evils quite in the same light as the Commissioners. No doubt the district medical officer who is not seeking general practice through his Poor-law office is in a more independent position than a private practitioner, but it is a great mistake to imagine that even he can afford to follow the lines most favoured by the Commissioners, and they must not forget that if the pauper patient does more frequently change his doctor it may be because the district medical officer does occasionally rise above the mere "bottle of medicine" treatment. *It is untrue to say that* the district medical officer does not take cognisance of the sanitary surroundings of the patient and is careless as to future illness. It is often from the district medical officer that the medical officer of health gets the first intimation of dangerous sanitary defects, and if his first duty is to treat the immediate illness of his patient he is seldom chary of pointing out bad habits and advising their abandonment. But in too many cases it is obvious to him that his advice under the circumstances is practically useless. These are the charges, if charges they can be called, against the efficiency of the district medical officer, that in the opinion of the Majority of the Commissioners warrant the abolition of his office and the transference of his duties to any practitioner willing to undertake Poor-law work.

But as there is a divided opinion it will be necessary to examine the views both of the Majority and Minority. The Majority propose to treat all Poor-law patients in provident institutions, the State paying the contributions of the Poor-law patients, who are to be allowed to choose their own doctors. As all the doctors in the district may, if they like, attach themselves to these institutions, every practitioner can become a Poor-law medical officer. Such a scheme, in my opinion, is as impracticable as it is undesirable. It clashes at once and is inconsistent with other recommendations of the same Commissioners, who are all agreed as to the necessity of an increase of State inspection of Poor-law medical work. Where nearly all medical practitioners are Poor-law medical officers, how could such inspection be carried out? Again, the expense would be prohibitive. Let it be clearly understood from the outset that no such scale of fees as is paid by the contributories to provident dispensaries would be acceptable to medical practitioners undertaking Poor-law work. The rate would have to be much higher, as much more work would be required. All the criticism directed against the work of the present district medical officers by the Commissioners tends to show that medical treatment of the up-to-date provident dispensary would not be sufficient for the State contributories. No one who has any experience of provident dispensary work could truly assert that the treatment there was superior to that given at the Poor-law dispensaries, or that the "bottle of medicine" figured less extensively. Then there would be the little official extras which would have to be paid for—I refer to the keeping of special registers, official reports, &c., no mean item in the work of the district medical officer. It is easy to see that, whatever mode of payment is decided upon, the new system would not be cheaper than the old.

Then as to the utility of the change, is it desirable? Pauperism is a social disease of a very contagious character. For that reason, according to modern doctrines, it should be isolated. If paupers are to be thrust upon provident institutions it must be greatly to the danger of the latter. An infection will have been introduced into a medium where it would be likely to spread like wildfire, and a very potent vaccine indeed would have to be found to inoculate a large portion of the poorer dispensary members to prevent them from seeking to join the ranks of their fellow State-paid contributories.

Then, speaking for the metropolis, I think I am correct in saying, that provident dispensaries have never been a success. The supporters of these institutions have found it more difficult to organise them successfully here than in other parts of the country. An endeavour to graft Poor-law relief upon them would, in my opinion, add considerably to this difficulty. At the present time there are practically no provident dispensaries in the metropolitan area that could be used for this purpose, and if a special attempt were made to create them they would not be supported by the classes for whom such institutions are properly intended, but would result in another series of Poor-law dispensaries with no advantages over the present, and much more expensive. I cordially agree with the Minority Report where it expresses the opinion that the carrying out of a scheme of this kind would bring us "round again to a State medical service, but this time to one of gigantic proportions."

Another criticism, too, might be properly directed against the scheme of the Majority. On p. 290 (200) we read:—

> As regards a gratuitous medical service for the cure of disease, recognise the attraction of the proposal, but we are unhesitatingly opposed to it.

Yet what does it all directly tend to? Let it be granted that in accordance with the recommendations of the Majority we have a large number of dispensary Poor-law doctors, all competing one against another, all interested in getting as many Poor-law patients as possible It must further be noted that the Poor-law doctor will then be doctor and relieving officer combined, so that he can accept as a Poor-law patient any applicant he chooses. He will be paid at least as much for Poor-law as for other patients, so that it will not pay the doctor to be too critical in his selection. If it be urged that abuse can only occur on the first application and that improper persons will afterwards be weeded out by the Public Assistance officer, I can only answer that if the new officer resembles the old it is extremely unlikely. That official will be only too prone to endorse the doctor's opinion. It seems to me that large and widespread gratuitous medical attendance for the poorer classes would be the inevitable result of the carrying out the proposals of the majority of the Commissioners.

At this point it seems desirable to say a few words in reference to the recommendation that the doctor, and not the relieving officer, should in the first instance be the judge of the right of the applicant to claim State assistance. This recommendation has been made because of difficulties that have been shown to exist where the poor have not ready access to the relieving officer, and also because it is stated that many of the deserving poor shrink from applying to that official who would have no scruple in approaching the doctor. That further facilities should be granted in the former case may be freely admitted, but I have no hesitation in saying that the remedy is worse than the disease. While endeavouring to safeguard a comparatively small class of the State poor, the present security of the whole is threatened with regard to obtaining prompt and immediate relief. At the present time, if a legal order is presented to the district medical officer, however awkward or inconvenient the summons, the latter must attend. Under the new arrangement he need only do so if he considers the applicant entitled to his services. This may be a gain to the doctor, but it is by no means certain that it is good for the poor applicant. It is further certain that many more under the new arrangement would seek and obtain free medical relief, but by no means so certain that the increase would include any but an insignificant fraction of those properly entitled to relief who refrain from applying because of having to face the relieving officer.

I now come to the recommendation of the Minority—viz., to retain the Poor-law medical officers as a distinct State service, but to arrange them side by side with the sanitary State service as a branch of the public health department. This proposal is free from many of the objections I have above referred to, and at least, in my opinion, is practical and statesmanlike. In the first place, it recognises what I consider the *sine quâ non* of any system of Poor-law medical relief—that it shall be administered by a separate and distinct public service, in which the officers are removed from considerations inseparable from competitive medical practice, where proper Government inspection is possible, and where the mere "bottle of medicine" treatment, if not entirely done away with, may at least be kept within moderate limits. In other words, it does not propose to destroy the present service, but rather to utilise it in a somewhat different manner. It is true that one of the tendencies would be to make the district medical officership a whole-time appointment and to debar the district medical officer from general practice, but I am not sure that under the present system the tendency is not in that direction. It also might encourage too freely gratuitous medical relief. If the Poor-law medical service, when ranged side by side with the public health medical service, were to minister relief as freely and gratuitously to all classes of the community as is done now by the latter, great dangers might arise. If thereby a higher degree of physical health were attained by the people, it would, in my opinion, be dearly paid for by undermining their independence and pauperising the lower classes of the nation.

On the whole, I am in favour of a continuation of the present system, but with suitable reforms. There are many abuses to be removed and necessary adjustments to be made to meet the requirements of the present day. But I do not think that its fundamental structure is likely to be bettered. As to what authority our service is placed under is a secondary consideration. In no other public service is practical experience in its official work and administration more important, both in the interests of the poor and of the public, and consequently long and faithful service under the Poor-law should be rewarded, as in other public services, by increase of salary and improvement of status.

None of us who have studied the careful and elaborate report of the Commission can fail to recognise the great value of the labours of the Commissioners. Their report is a vast storehouse of facts, throwing much light on the condition of the poor throughout England and Wales. We only demur to the way in which these facts have been employed in elaborating arguments for the sweeping changes proposed in our service. Speaking generally, I think it will be found that nearly all the members of our service would regard favourably most of the proposals of the Commissioners that have met with the unanimous support of the whole body.

Hackney-road, N.E.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

THE PRISM AS AN AID TO DIAGNOSIS IN PARALYTIC DIPLOPIA.

By R. BRUCE FERGUSON, M.A., M.D., B.C. CANTAB., D.P.H., &c.,

FORMERLY HOUSE SURGEON TO THE ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; CLINICAL ASSISTANT, ROYAL LONDON (MOORFIELDS) OPHTHALMIC HOSPITAL, ETC.

ONE occasionally comes across a case of diplopia which seems to transgress all the established rules regarding the position of the false image, and which defies all attempts at making an accurate diagnosis as to the particular muscle at fault. Such a case I have lately had under my care.

The patient was a healthy man, aged 36 years. The right eye was the one affected, and the diplopia appeared rather suddenly, without obvious cause. There was no ptosis or alteration in the pupil; no sign of optic neuritis or other fundus change. I examined him in the usual way, placing a red glass in front of the right eye. When a light was held directly in front of him the false image was displaced downwards and to the left ("left" and "right" here refer to the patient's left and right), and on moving the light to the left, the false image retained the same position. It thus seemed perfectly obvious that I had to deal with a case of paralysis of the inferior rectus. But on bringing the light to the right, the false image at once changed its position, being displaced downwards and to the right, the former crossed diplopia thus becoming homonymous, and paresis of the superior oblique being indicated with equal certainty. This test was repeated on several occasions, and always with the same results. The patient was unable to perceive any increase in the amount of lateral deviation of the false image on moving the light further from the middle line to either side. The question thus arose, which of the two muscles was at fault? Both were probably not affected, since it was difficult to conceive of a lesion which, whilst involving the fourth nerve, should also involve only that branch of the third nerve which supplies the inferior rectus, as shown by the total absence of all other symptoms of third nerve paralysis, such as ptosis or pupillary changes.

I next proceeded to ascertain what could be done in the way of correcting the diplopia with the aid of prisms, and I found that a prism of 6°, base downwards and outwards, and its axis making an angle of 60° with the horizontal, gave a perfect correction. In fitting a prism, the rule is to turn the base in the direction of action of the paralysed muscle. In this case the base was turned down and out; the action of the superior oblique is to turn the eye downwards and outwards. The diplopia was thus entirely corrected by treatment such as would be adopted in an uncomplicated case of paresis of the superior oblique; and the point arises, is one justified in assuming that paralysis of a particular muscle is present, on the ground that treatment for paralysis of that same muscle is alone effective in removing all symptoms? If this assumption be legitimate, and I think it is in the case of the eye, the individual muscles of which possess such distinctive actions, then we have in a prism a most valuable aid to diagnosis in doubtful cases, since it is only necessary to find the prism which corrects the diplopia, and then by noting the direction of its axis and the position of its base, one is at once enabled to state which is the affected muscle.

It is probable that attention has been drawn to this point before, though I am not aware of the fact, nor have I found any reference to it in the text-books. I may add that I prescribed prisms of 3° for each eye; these enabled the patient to attend to his business in great comfort, which he was totally unable to do before; meanwhile slow improvement is taking place under potassium iodide.

New Southgate, N.

A CASE OF RUPTURED UTERUS WITH PERFECT RECOVERY.

By R. N. GEACH, M.R.C.S. Eng., L.R.C.P. Lond.

ON Jan. 28th of this year I was called to see a woman who was in labour. The story of the woman in attendance was that shortly after her arrival the patient began to feel very ill, and complained of acute pain low down in the right side of the abdomen. The labour pains stopped completely, and the woman complained of feeling very cold and sick. Shortly after this she vomited. The lips and cheeks were blue and the face was very pale. On arrival I found the woman in a very collapsed condition, and suspecting some mischief present I proceeded to deliver with forceps, but having some difficulty in keeping them on the head I performed internal version and delivered. The placenta not being born naturally I inserted my hand, previously very carefully made aseptic, in the uterus to remove it and then found a large rent in the posterior wall of the uterus, about six inches long, commencing from the vagina and running upwards [illegible] Having removed the placenta [illegible] serious condition of the patient, [illegible] active surgical treatment, and merely placed the edges of the rent in the uterus in apposition; I did not douche or put in a drainage-tube. When I left the house the patient's condition was desperate, a running pulse, cold extremities, blue face and lips, and shallow breathing. This condition continued for 48 hours, accompanied by a certain amount of abdominal pain, chiefly in the right iliac region. On the day after delivery I showed the case to Mr. H. P. Symonds of Oxford, who agreed with me as to the bad chance of recovery. *On the third day after delivery the patient rallied*, and the symptoms of shock passed off, and then commenced a condition of subacute peritonitis, lasting for three weeks. Champagne and brandy were freely given, and for several days she lived on those stimulants and a small amount of milk and barley water. The temperature varied between 99° and 103° F., with a very feeble and rapid pulse. Cystitis was a complication of the case and there was much vomiting. The temperature came down to normal at the end of the third week, and after another fortnight the patient was able to leave her bed. At the present time the woman is in very fairly good health and performing her usual household duties.

Charlbury, Oxon.

A CASE OF SPASMODIC TORTICOLLIS FOLLOWING CHOREA.

By T. E. LISTER, M.B., Ch.B. Leeds,

SENIOR HOUSE SURGEON, CLAYTON HOSPITAL, WAKEFIELD; LATE RESIDENT OBSTETRIC OFFICER, THE GENERAL INFIRMARY, LEEDS

THE patient, a boy, aged 17 years, first began to have spasmodic contractions of both sterno-mastoid muscles alternately about the beginning of April of this year. The condition gradually became worse until April 15th, when he was brought to the out-patient department by his mother. He had two years previously been in the hospital for chorea, which he had *very severely. On April 15th the patient* was put on to the following mixture: pot. brom., gr. xv.; liq. arsenicalis, ♏ iii.; aq. ad ℥ i.; t.d.s. He came to the out-patient department a week later feeling much better, the severity and frequency of the attacks being less. The medicine was repeated, but during the next week he became very much worse and came to the hospital and was admitted.

On admission the patient was very pale and thin. He had very light-coloured hair and was obviously under-developed, having no pubic or axillary hair, and weighing only 4 stones 7 pounds. The spasm affected the sterno-mastoid and also the deeper muscles of the neck, *together with the platysma myoides. At the same time* that the face was forcibly jerked over to the opposite shoulder the patient took a sharp, short inspiration, proving that the inspiratory muscles were affected. The spasm appeared to occur more frequently on the left side, thus jerking the face to the right, but both sides were affected. The successive spasms varied in intensity, some only bringing the chin *slightly towards the right, whilst others brought it into* line with the occiput and the right shoulder. During the spasm the boy's face became paler and the lips distinctly blue. The spasms were more frequent if the patient were being watched or if he became excited. The spasms were so bad that it was almost impossible to feed the patient, and he was not able to hold anything in his hand; *they, however, disappeared during sleep.* The depressor muscles of the inferior maxilla were affected, for at the same time that the inspiration was made the mouth was jerked open. No abnormal signs were found in the skin or deeper parts of the head and neck. There was an oval-shaped prominence over the cardiac area on the left side of the sternum, including the second, third, fourth, and fifth *costal cartilages. It extended from the sternum almost to* the mammary line at its widest part. The cardiac dulness was normal and the apex-beat could be felt at the nipple line in the fifth interspace. There were no abnormal pulsations seen over the cardiac area and no thrill could be felt. The first sound was rather weak at the apex. Over the tricuspid area there was a distinctly snapping second sound. There were *not any bruits heard. There was pulsation in the large* veins of the neck. The knee-jerks were normal, there was no ankle-clonus, and Babinski's sign was absent. No other abnormal signs were found.

Progress in hospital.—On May 5th the spasms had gradually become weaker and fewer. On the 7th no spasms were seen, but a slight twitching of the inferior maxilla was occasionally seen if the patient became excited.

Treatment.—On admission the patient was put to bed in a private ward away from the other patients. Light diet was given, together with the following: Sodii salicylatis, gr. xv.; aq. chloroformi ad ℥i., t.d.s.; virol, ʒi., t.d.s. These medicines were continued until the patient's discharge on May 29th. For three weeks before discharge he had had no spasms and there have been none since.

The special reasons for reporting this case are: that it is unusual to find spasmodic torticollis in a patient so young; also the close connexion which this case seems to have with chorea, which the boy had previously; and, thirdly, the speedy recovery which took place, most cases being particularly intractable.

I am indebted to Dr. F. H. Wood for his kind permission to publish the case.

Wakefield.

Medical Societies.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Fevers in Rangoon.—Preventable Diseases in Siam.—A Case of Amœbic Abscess of the Spleen and a Case of Blackwater Fever.

A MEETING of this society was held on July 16th, with Sir PATRICK MANSON, the President, in the chair.

Lieutenant-Colonel J. R. FORREST, R.A.M.C., sanitary officer, Burma Division, communicated a paper on Fevers in Rangoon. In Rangoon they had not yet emerged far from the period when every case of fever was returned under one of three headings: (1) malaria; (2) simple continued fever; and (3) enteric fever. A further classification, based on easily recognisable features, would not only tend to a clear conception of the fevers with which they had to deal, but would modify and improve treatment. Nowadays it was quite insufficient to return a fever under the heading "malaria." Every medical officer ought to be capable of saying whether a case of malarial fever was (1) simple benign tertian; (2) benign tertian with double infection;

(3) malignant tertian; or (4) quartan. No case ought to be returned as malaria in which the temperature had been unaffected by four days' treatment with quinine, in doses of at least 30 grains a day. It was essential to point out that a case was not necessarily malaria because it had failed to give a positive Widal reaction, yet that was the conclusion to which many diagnosticians seemed to come. Cases were often returned as "dengue," which, he maintained, were not "dengue"; and that because the characteristics of dengue were forgotten or ignored. Dengue was a three-day fever, with a primary and often a secondary rash, with a secondary rise of temperature, the pains were excruciating, and the disease was epidemic. Many of the cases returned as "dengue" were really instances of "pyrexia" of uncertain origin—i.e., to be further differentiated. Moreover, there were in Rangoon many typical cases of what Rogers had called seven-day fever. The saddle-back depression in the temperature curve could not be mistaken. There were general pains, and temporal headache was commonly severe, but the agonising "breakbone" pains of dengue were absent. Microscopically, there was a diminution in the number of polynuclear leucocytes. There was also a fever in Rangoon which did not present the temperature curve of seven-day fever, nor the characteristic signs and symptoms of dengue. It occurred during the rains, ceasing early in September. The temperature curve was like a parabola in form; it might rise to 103° or 104° F., and the course of the fever might extend from three to 14 or 15 days.—Dr. J. L. **Maxwell** pointed out that a better definition of fevers was required.—Dr. C. F. **Harford** said that there were not sufficient data for a proper classification.—The **President** agreed that it was impossible to attempt to classify the fevers in the East because of the want of accurate information.

Dr. P. G. **Woolley** communicated a paper on Preventable Diseases in Siam, in which the value of modern sanitary measures was described. He considered that because gastro-intestinal diseases caused more than half the deaths in Siam, therefore that mortality could be ascribed to water-supplies and was due to preventable causes.

Dr. **Maxwell** read a paper by his brother, Dr. J. **Preston Maxwell** of Amoy, on two rare cases from the Fuh-Kien Province, South China. One was a case of Amœbic Abscess of the Spleen in a Chinaman. The splenic tumour filled the left half of the epigastrium and projected into the right thigh. After an operation, in which 80 ounces of pus were evacuated, the patient recovered. Amœbæ similar to those found in the stools of the patient were discovered in scrapings from the wall of the abscess cavity. The cause of the splenic abscess was ascribed to direct infection from the splenic flexure. The second case was one of Blackwater Fever in a patient who had had attacks of malarial fever that had been insufficiently treated with quinine. When the patient was attacked with the blackwater fever he was given a mixture containing spirit of nitrous ether and spirit of chloroform. The urine slowly cleared and he gradually recovered strength and returned home. Blackwater fever, in spite of the severity and fatality of malarial fever in some parts of the province of Fuh-Kien, was an almost unknown disease there.—Dr. W. **Carnegie Brown** observed that the capsule of the spleen seemed to him to offer sufficient protection against infection from the splenic flexure in a case of amœbic abscess of the spleen.—Dr. J. L. **Maxwell** could not imagine the infection spreading from the splenic flexure. It seemed to him more likely that the infection was carried by the blood-stream.—The **President** said that he suspected that occasionally these sporadic cases of blackwater fever were examples of paroxysmal hæmoglobinuria.—Mr. J. **Cantlie** said he had seen cases of blackwater fever in China in which there was no doubt about the diagnosis. He had treated a case of blackwater fever successfully by giving ten drops of turpentine every four hours.—Dr. **Oswald Baker** said that the geographical distribution of blackwater fever should be accurately determined, and Dr. **Harford** discussed the prophylactic use of small doses of quinine after an attack of blackwater fever.

Mr. J. Sewell, honorary veterinary surgeon to the Zoological Society, has recently performed the minor operation of cutting the overgrown claws of a large lioness after the animal had been anæsthetised in a "chloroform box."

Reviews and Notices of Books.

Moral Instruction and Training in Schools: Report of an International Inquiry. Edited by M. E. **Sadler**, Professor of the History and Administration of Education in the University of Manchester. London: Longmans, Green, and Co. 1908. Two volumes, pp. 538 and 378. Price 5*s.* net each volume.

The two volumes under consideration contain the written reports and the papers read at the International Congress which met in London in the autumn of 1908 to consider the question of moral instruction in schools. There is an introduction by Professor Michael Sadler, in which the evidence brought forward is summed up impartially and clearly, and the origin and *raison d'être* of the congress is described. In 1906 a number of people interested in education met in London to discuss whether "more might not be done by means of moral instruction and training in schools to impart higher ideals of conduct, to strengthen character, and to promote readiness to work together for social ends." So diverse were the opinions in the ensuing discussion that it was deemed advisable to institute an inquiry into the subject of moral instruction in the schools of the United Kingdom and other countries. A council was formed of many hundreds of people, representing all forms of educational experience. Professor Sadler states that "no more representative a council has ever been formed for the investigation of an educational problem in this country." Certainly the matter and method of attacking the problems of moral instruction in the two volumes are as varied as are the people and nations from whom the reports are sent. Not only are all grades of schools represented, primary and secondary, public and private, the pauper and the well-to-do, but all lands from East and West—France, Germany, Switzerland, Norway and Sweden, Denmark, Belgium, America, Canada, Australia, New Zealand, and Japan. It follows necessarily that all points of view are represented, though the different teachers hold different opinions as to the ultimate authority on which morality is based, whether prudential, personal, social, or religious. But whatever their diverse opinions as to the origin of morality, all are agreed that in order to obtain the best out of an individual, both for himself and for the community, it is necessary that the schools should give moral instruction; this most important part of education cannot be left entirely to parental discretion. If the State simply compels the child to have its intellectual faculties trained without giving any indication as to how those faculties may be employed usefully and happily for the community there is certain peril both to the individual and to the State. Though the necessity of moral training is strongly urged in all the reports, there is a diversity of opinion expressed as to whether the instruction should be given directly or indirectly. Direct moral instruction includes parables, talks, or systematic lectures on the virtues—for example, on honesty, thrift, kindness, patriotism, and civic and family duties. Indirect moral instruction includes (1) the cultivation of many-sided interests; (2) the provision of moral atmosphere; and (3) moral training in good habits. Both systems can claim excellent results. From a perusal of the reports we gather that, broadly speaking, in schools with pupils derived from the British middle or wealthy classes, where there is an atmosphere of culture, manners, and refinement in the homes, it is better to teach morality indirectly, but in schools with pupils drawn from our social substratum it is more necessary to give direct instruction in manners and morals.

The importance of combining education of the body as well as of the intellect for the benefit of the scholar's *morale* is demonstrated by Mr. Legge (director of education of the city of Liverpool), who describes the results obtained by the reformatory and industrial schools. In these schools the day was divided into two parts, one of which was devoted to literary and intellectual work, the other to practical and constructive work of a kind calculated to stimulate the interest, hold the attention, and promote the development of the reasoning powers. After five years' trial it was found that the ordinary school work had risen in standard, but more marked still was the increased moral well-being. The children's pride in their honest work had influenced their characters for the better. Quite as impressive were the effects of physical training. "Firm flesh, straight bodies, heads erect, hale complexions, intelligent eyes, and a ready smile; these characteristics were found nearly always to imply in the doctor's book an almost clean sheet, and in the record of conduct little absconding, few offences against morality, next to no bullying; only an occasional case of pilfering or lying." Mr. Legge quotes John Milton, who urged that exercises "will keep them healthy, nimble, strong, and well in breath; is also the likeliest means to make them grow large and tall, and to inspire them with a gallant and fearless courage, which being temper'd with seasonable lectures and precepts to them of true fortitude and patience, will turn into a native and heroic valour, and make them hate the cowardice of doing wrong."

The effect of direct moral instruction based upon purely intellectual and upon religious grounds is well illustrated by the reports from France and Japan respectively. Both are worthy extensive quotation. Mr. Harold Johnson writes a very exhaustive account of the French method, where the moral lessons are often given in a prevailingly sceptical atmosphere. "Be reasonable" is often the final appeal. "No child," says Mr. Johnson, "need leave the primary school in ignorance of the fundamental moral distinctions. ...... Teacher and pupil in the *lycée* and Normal College revel in the subtlest dialectic in truly Socratic fashion and grapple with the profoundest moral problems. ...... This procedure appears to be followed by *quite fatal results. Montpellier reports that most of the professors* admit not having observed any appreciable progress in the character of their pupils as a result of the lessons (given since 1902). One remarked that 'my prizeman in *morals is the biggest knave of the lot.*'" Mr. *Johnson* concludes that while the intellect is crammed with moral problems the physique is neglected and the moral lessons are not brought into active virile contact with the pupil's real life. The moral lessons deal with the homely and prudential virtues, neglecting the larger ideals that give scope to the imagination and draw out the disinterested and higher qualities of human nature. Mr. Reginald Balfour concludes his inquiry into the French system with very similar criticism: "All moral instruction, given without the sanction and appeal to more sacred claims than those of duty to the community or to self, is quite inadequate for its object, namely, the formation of individual character and the foundation of national virtue."

Contrast this state of affairs with that met with in Japan. In that country the child receives, as well as careful direct moral instruction, training in physical development, while love of art and beauty are inculcated into the lessons on manual work, agriculture, and commerce The duties of citizenship are taught to every child. Baron Kikuchi (p. 319, Vol. II.), Minister of Education in Japan (1901–03), contributes the report *on the spirit of Japanese* education. He states: "The effectiveness of the moral teaching in our schools is very largely based upon the almost religious attitude towards the Emperor, and it is effective because the moral instruction in Japan is based upon something very similar to what you would call in England a 'religious sanction.' ...... In Japan we talk of duty, of what we have to do, and we talk very little of rights." The teaching of morals is based on the Imperial Rescript on Education, which, published in 1890, saved the State from drifting away after the inevitable sapping of the old foundations of morality by the Restoration in 1868, when the military class lost their privileges and nothing had been found to take the place of the old Chinese philosophy.

Denmark leads the van in the teaching of what may be called the personal virtues closely connected with the rudimentary facts of life, facts which most nations and individuals either ignore or regard as unable to be dealt with. In the reports from Denmark the subject of sexual hygiene is not regarded as an inexplicable and troublesome problem which individuals must worry out as best they can. In the Danish view, as well as in that of many of our sanest thinkers, it is ignorance that is the cause of the social problem which is the canker at the heart of high civilisations. For the well-being of the individual it is essential that these matters should be placed on a high plane, not relegated to holes and corners. Clear and early instruction is the only chance of raising the moral tone of a nation, of leading to happy manhood and womanhood, and to a purer family foundation. Co-education is general in Denmark. In other countries also, where it has been tried not from motives of economy but from the high ideal of a noble sex-comradeship, the results have been eminently satisfactory for both sexes. The Rev. C. Grant (Harpenden, Herts) writes (Vol. I., p. 248): "If a wise system of co-education were universal in England sexual immorality ...... would become as extinct as hydrophobia now is." This is, of course, a too summary pronouncement, and leads us to suppose that Mr. Grant is not wholly familiar with the situation. The medical profession, who in the near *future will have more influence in schools,* both at home and abroad, than they have hitherto had, know well the difficulty of the problem that lies before those who would instruct the young in the problems of sex, and a majority of *them would probably consider that co-education of the* children made the problem no simpler.

We heartily recommend these volumes to all members both of the teaching and of the medical profession.

Mitteilungen aus der Augenklinik des Carolinischen Medico-Chirurgischen Instituts zu Stockholm. Edited by Dr. J. WIDMARK, Professor of Ophthalmology at the Institute. Ninth Fasciculus. With one plate and 12 figures in the text. *Jena: Gustav Fischer.* 1908. *Pp.* 130. *Price* 5 marks.

OPHTHALMOLOGISTS are familiar with the valuable communications which are issued from time to time from Professor Widmark's Clinic at Stockholm. We do not commend this method of publication, for there are so many good journals devoted to ophthalmology, to which reference is naturally made for recent work on any subject, that these by-products are likely to be overlooked. Moreover, unless they are very freely distributed they may be difficult of access. Widmark's "Mitteilungen," however, are so highly esteemed that they have now attained an assured place in the literature and will be found in most good ophthalmic libraries.

The present fasciculus contains three papers by the editor. The first deals with a case of bilateral detachment of the retina, which underwent what may be regarded as spontaneous cure, *a fact which those conversant with the malady* will consider sufficient reason for publication. The condition appears to have been due to retrobulbar inflammation originating in the ethmoidal and other accessory sinuses of the nose. Two other cases from a similar cause are recorded in the literature, and in both the retinal detachment disappeared. This result, so at variance with that to which we are accustomed, places the cases in a group apart. The possibility of actual indentation of the walls of the globe by an inflammatory deposit, and not a true detachment of the retina, is not considered by the author. Professor Widmark's second paper reports three cases of toxic amblyopia of unusual etiology. Two appear to have been due to the inordinate consumption of coffee, one probably to poisoning with arsenic. The third communication discusses the treatment of sympathetic ophthalmia with sodium salicylate, and extends the observations of Lindahl in a previous fasciculus of the Mitteilungen. The author obtained unusually good results and commends the use of the drug in these troublesome cases. This paper also contains some interesting statistics. Lindahl contributes two papers on the action of lacrymal secretion upon bacteria. Many investigations have been carried out on this subject with ambiguous results. Lindahl finds a definite slight antiseptic effect upon ordinary pyogenic organisms, due to an enzyme. He also shows that human tears contain active agglutinins against staphylococci. Forsmark reports a case of bilateral symmetrical epibulbar leucosarcoma, with details of the histological structure. Gertz describes an apparatus for the estimation of refraction by use of the inverted ophthalmoscopic image. The instrument, which is called the parallax-optokrit, is not likely to replace the retinoscopic mirror. Lamm records two cases, one of a slight congenital malformation of both optic discs, probably remnants of the hyaloid arteries, the other an orbital tumour.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. An Inquiry on Enteric Fever in India carried out at the Central Research Institute, Kasauli, under the direction of Lieutenant-Colonel D. SEMPLE, R.A.M.C., M.D. R.U.I., Director of the Institute; and Captain E. D. W. GREIG, I.M.S., M.D. Edin. No. 32. Calcutta: Office of the Superintendent of Government Printing, India. 1908. Pp. 108. Price R. 1 annas 2, or 1*s.* 2*d.*

FOR a long number of years the etiology of enteric fever has been a fruitful subject of discussion in India. The question has gone through many stages. Thus at one time in Madras Surgeon-General A. Gordon, principal medical officer of Madras, laid it down that there was no such disease as enteric fever in India; to whom succeeded Sir Anthony Home, who, when principal medical officer of His Majesty's Forces in India, issued an order that all cases of fever in which at the post-mortem examination ulceration of the intestines was found were to be returned as cases of enteric fever, no matter what the nature of the ulceration. Naturally, under Home the cases of enteric fever appeared to greatly increase. Then we had that theory so beloved by the Government of India at one date, and which took various verbal forms, such as—that enteric fever was due to "climatic causes"; "that typhoid fever in India is primarily due to climatic influences"; that "geographical position and climatic influences, heat, moisture, organic decomposition, miasmata, and a variety of aerial and telluric conditions are more likely than a specific cause in India." But happily now we are less imaginative, and it would seem that there is nothing so mysterious concerning the prevalence of enteric fever in India. Under the wise initiative of Lord Kitchener an exhaustive inquiry was ordered on the subject in India.

The inquiry, the results of which we are now reviewing, was commenced in April, 1906, at the Central Research Institute, the officers participating in it being Lieutenant-Colonel Semple, the director of the institute; Captain E. D. W. Greig, Lieutenant-Colonel F. Wyville Thomson, I.M.S.; Captain D. Harvey, R.A.M.C.; Captain F. N. White, I.M.S.; Captain E. C. Hodgson, I.M.S.; and Assistant Surgeon Paras Ram. The essential matter to discover was the storehouse of the virus of enteric fever, and consequently the persistence of the disease amongst the troops in cantonments. General sanitary measures only could be adopted for the prevention of the fever in absence of any precise knowledge, and the results of these were not very satisfactory. In 1902–03 Koch commenced his important investigation into the etiology and spread of the disease and at length evolved two very important facts—viz., (1) that the saprophytic existence of the parasite outside the body is very short; and (2) that it lives in the bodies of men for a long time after they have acquired immunity from the disease. So that man, in fact, is the storehouse of the virus, from which he infects susceptible individuals. The conditions as regards enteric fever in Alsace Lorraine appeared to be very similar to those met with in Indian cantonments, and as Koch's precautions against the disease were here very satisfactory Captain Greig was deputed by the Indian Government to proceed to Germany to study the methods on the spot. In 1906 an inquiry into the causation of enteric fever was commenced at the Central Research Institute, Kasauli, and the problems to be solved were: (1) the nature and duration of the saprophytic life of the bacillus typhosus; (2) the duration of its life within the human host; (3) the way in which epidemics are produced. As the result of the inquiry, in which full use was able to be made of Koch's experience, it has been determined, amongst other facts, that the bacillus typhosus continues to be excreted for long periods in the urine and fæces of a certain percentage of the convalescents; that the number of bacilli in the urine is very large; that the "chronic bacilli carriers" are the cause of epidemics; and that enteric fever orderlies may become "chronic bacilli carriers" without having passed through an attack of the disease. Consequently the Commission recommends that the urine or fæces of all convalescents should be submitted to a careful daily bacteriological examination for a prolonged period. A special body of trained men for the purpose of nursing enteric fever patients should be found, for otherwise these "chronic bacilli carriers" under the present system at the end of their period of duty as enteric nursing orderlies return to their units and so become fresh foci of infection. This must for the future be obviated. Lastly, all men—European and native—must be subjected to a careful bacteriological examination before they are permitted to be employed in connexion with the preparation and distribution of food and drink to their comrades.

This report is a most excellent piece of work, the results of which are bound to be beneficial to our Indian Army, but it requires little insight to perceive that difficulties of administration would follow upon the adoption of some of the recommendations.

A Treatise on the Principles and Practice of Medicine. By ARTHUR R. EDWARDS, A.M., M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Northwestern University Medical School, Chicago. Illustrated. Edinburgh and London: William Green and Sons. 1908. Pp. 1328. Price 33*s.* net.

THIS text-book is written on sound and well-reasoned lines, adequate attention to scientific theories being subordinated to the discussion of the cure or the alleviation of disease. Accordingly, an unusual amount of space has been devoted to treatment, to the detailed consideration of drugs, and to numerous formulæ and prescriptions suitable for the practitioner to use or improve upon. The physiological action of drugs is considered at length, the author's reason for taking this course being that he believes the symptoms of disease are more often confounded with those of the remedies exhibited for its cure than is quite creditable to therapeutics.

The various diseases are considered in the manner usually adopted in text-books on general medicine with the exception that the causative pathology has been blended with the consecutive clinical features of the disease. The general plan which is adopted may be best explained by taking one disease as an example, and we have selected pleurisy for this purpose. The *definition* is first given—"an inflammation of the pleura, rarely primary but usually secondary to tuberculosis or other lung disease, general infections, septicæmic affections, and various diseases in contiguous tissues or organs." The *etiology* is then considered in a very comprehensive manner, the associated pathological conditions being fully indicated. The *bacteriology* is next discussed, attention being drawn to the fact that the etiological classification already given does not correspond to the bacteriological division. The *symptomatology* (which includes the physical signs) is given in great detail, and certain phenomena are mentioned which are not found in recent text-books, such as the rhythmic lateral displacement of the heart which is often marked in medium-sized effusions. *Special forms* of pleurisy are next described. Emphasis is rightly laid on the value of cyto-diagnosis. It is now generally recognised that the presence of an increased number of lymphocytes is characteristic of primary tuberculous pleurisy and affords diagnostic data before the results of inoculation are available. The differential *diagnosis* is well given, and the various difficulties which arise are duly dwelt upon. After a few remarks on *prognosis* the *treatment* is adequately discussed. It will thus be seen that Dr. Edwards carries out his task with systematic thoroughness, while a full index adds to the value of the book.

Lehrbuch der Ohrenheilkunde für Studierende und Aerzte. (Text-book of Aural Therapeutics for Students and Practitioners.) By Dr. GEORG BOENNINGHAUS, Lecturer on Otology; Aural Surgeon at St. George's Hospital, Breslau. With 139 figures in the text and one coloured plate. Berlin: S. Karger; London: Williams and Norgate. 1908. Pp. 376. Price 9 marks 80 pfennig.

Dr. Boenninghaus commences with a description of otoscopy, and in this chapter there is the time-honoured illustration, so common in most books on otology, rhinology, or laryngology, which shows how the light is reflected from a mirror into a cavity. But there is one point mentioned here in connexion with the examination which is rarely considered in works of this description—namely, the examination of the membrana tympani with a powerful magnifying glass, that which is recommended as being most serviceable being one of 7½ centimetres and 13 diopters. The second chapter is on the parts seen, and the information to be derived therefrom in the otoscopical examination. This part of the book contains many points of interest, and shows an unusual minuteness of observation, together with an ability to record its outcome, as is seen in his consideration of the various angles of the malleus, the shape and sizes of the cone of light, the variations in the short process or in Shrapnell's membrane, or in the stria malleolaris, &c., all of which are carefully illustrated by means of diagrams. The functions and testing of the ear form the subject matter of the third chapter, in which there are many very interesting points which will well repay careful attention. We may especially mention the part in relation to accommodation. It is interesting to note that the tuning-forks recommended vary from C, having 16 vibrations, to C^8 in the treble, having 32,768 vibrations—a much higher tuning-fork than we are in the habit of using in this country. And in contra-distinction to the teaching of Bezold the writer prefers to use the octaves of A, and we may here incidentally remark that in all probability in a noisy place the octaves of A are superior to those of C for the purposes of investigation. Here also we find an extremely valuable contribution to the differential diagnosis between middle-ear and labyrinthine deafness. Moreover, the methods of testing the integrity of the labyrinth are very clearly set forth.

The second part of the book, of which the fourth chapter forms the commencement, is devoted to the special pathology and therapeutics. The fifth chapter is concerned with diseases of the middle-ear, and begins with a description of its anatomy and physiology. In these two chapters there is but little that is novel. After a very excellent *résumé* of the present knowledge of otosclerosis, the sum total of the treatment, according to Dr. Boenninghaus, is massage, by which it is hoped to mobilise the stapes. The sixth chapter deals with diseases of the internal ear, the more modern treatment of attacking the vestibule for vertigo and the cochlea for tinnitus being recommended. The operative methods are dealt with in a separate chapter, and there is a very beautiful plate with 28 coloured illustrations of the tympanic membrane at the end of the book. There is so much in Dr. Boenninghaus's book which is novel, and such frequent evidence of an intimate acquaintance with his subject, that no aurist will be able to peruse it without pleasure and profit.

LIBRARY TABLE.

The Sanitary Officer's Handbook of Practical Hygiene. By C. F. WANHILL, Major R.A.M.C., M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Conjoint Board of England, Assistant Professor of Hygiene at the Royal Army Medical College; and W. W. O. BEVERIDGE, D.S.O., Major R.A.M.C., M.B., C.M. Edin., D.P.H. Camb., F.C.S., Analyst to the Army Medical Advisory Board. London: Edward Arnold. 1909. Pp. 151. Price 5*s.* net.—This is a compact handbook of practical hygiene, written by two officers of the Royal Army Medical Corps with the object of supplying an epitome of the laboratory technique covering the examination of water-supplies, sewage, ventilation, calculation of diets, bacteriological problems, and the analysis of foods and beverages. The general scheme is that on which the training in the hygiene laboratories of the Royal Army Medical College is carried out, and which has been found to be satisfactory both for military purposes and for preparation for the Public Health Diploma examinations. The book is interleaved to allow of the reader adding further notes, and teaching of the subject is not attempted, it being assumed that the reader has had previous training and requires merely to refresh his memory with regard to details. Notwithstanding a few errors which appear, mainly of a typographical nature, and which may be regarded as inevitable in a first edition, we have formed a very favourable impression of the work; the authors handle their subjects well, the details of the technique of the various analyses are briefly but clearly described, and the condensation of matter is not unduly carried out.

Principles and Practice of Operative Dentistry. By JOHN SAYRE MARSHALL, M.D. Syr. Univ. Third edition. London and Philadelphia: J. B. Lippincott Company. With 725 illustrations. 1909. Pp. 654. Price 21*s.* net.—The title of this book is a little misleading, inasmuch as a large portion consists in an account of the anatomy and pathology of the teeth somewhat out of proportion to the amount of room allotted to the description of operative measures. We have, however, no quarrel with the author on this score, because he has provided some most excellent reading. The anatomy, development, and histology of the teeth are dealt with in the first four chapters; the descriptions given are good and the same may be said of the illustrations accompanying the text. There is a good account of the bacteriology of the mouth, while the section dealing with the pathology of the dental issues is all that one could desire in a text-book for students. The book, however, from the point of view of operative dentistry, is disappointing and leaves much to be desired. It is strange to find in a modern work the old turnkey advocated for extraction; we thought that such instruments were regarded as relics of the past.

Geschichte der Laryngologie an der Universität Heidelberg, seit der Erfindung des Kehlkopfspiegels bis zum erste Oktober, 1908. (*History of Laryngology at the University of Heidelberg from the Introduction of the Laryngeal Mirror up to October 1st, 1908.*) By Dr. JURASZ, Professor of Laryngology at Heidelberg. Würzburg: A. Stube. 1908. Pp. 54. Price 3 marks.—As the title implies, this is a short history of the laryngoscope from its introduction in Heidelberg up to the present time. The second chapter deals with the clinic from 1875 onwards, and contains amongst other things a list of the contributions to literature founded on the work of the clinic which have been published during this period. This is followed by a list of the lecturers and teachers, and the courses of study as they have varied from time to time. Chapter IV. relates to the question of a permanent laryngological clinic, and gives a *résumé* of the various discussions which have taken place in reference to this. The work is historically interesting.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXVIII., No. 6, July 2nd, 1909. London: Cambridge University Press Warehouse. Price 4*s.* 6*d.*—The contents of this number include the following:—1. The Coagulation of the Blood, Part II., the Actions of Snake Venoms, Peptone, and Leech Extract, by John Mellanby, M.D. Cantab., George Henry Lewes student. 2. On Degenerative Changes in the Nerve Endings in Striated Muscle, in the Nerve Plexus on Arteries, and in the Nerve Fibres of the Frog, by J. N. Langley, F.R.S. This number also contains the proceedings of the Physiological Society for May 15th and for June 5th, 1909, and the table of contents with list of authors who have contributed to the thirty-eighth volume. Dr. Mellanby's article is a long one, and we can only extract some part of the summary supplied by the author. He finds: (1) That the venoms of an Australian viper (Notechis scutatias) and an Indian viper (Echis carinatus) contain principles which generate fibrin ferment from prothrombin. They therefore coagulate any fibrinogen solution to which they may be added. Consequently their active principles are physiologically equivalent to a mixture of tissue kinase and calcium salt, and by analogy may be assumed to consist of substances containing kinase and calcium salt in union with one another. But owing to the paradoxical influence of potassium oxalate on these venoms (this salt largely increases their coagulating activities) the hypothesis is advanced that the active blood-coagulating agents contained in them consist of pure kinase and that the calcium salt necessary to work in conjunction with this kinase is present in the prothrombin or fibrinogen solution adsorbed by the protein. The author also finds (2) that the rapid injection of small quantities of these venoms results in extensive intravascular coagulation, this intravascular coagulation being due to the rapid production of fibrin ferment by the kinase contained in the injected venom and the consequent rapid production of fibrin. His other inferences are that (3) the slow injection of small quantities of these venoms results in the production of fluid blood (negative phase blood), for the ferment is only slowly formed and can be dealt with by the blood and tissues; (4) cobra venom, which does not contain an antifibrin ferment, prevents the coagulation of blood by means of an antikinase; (5) peptone blood coagulates on adding to it birds' fibrin ferment (it does not contain a greater quantity of antifibrin ferment than normal blood derived from the same animal); (6) hirudin contains both an antikinase and an antifibrin ferment.

British Journal of Inebriety.—The July number of this journal contains an article on the Scientific Study of Alcohol and Alcoholism, which gives a brief account of the organised efforts that are being made in this and other countries to promote the study of the alcohol question on scientific lines. The facts set out in the article, which in view of the London meeting of the International Congress on Alcoholism has a very timely interest, will come as somewhat of a revelation to many persons who have been accustomed to associate the literature of this subject with the outpourings of the teetotal orator. It will be an agreeable surprise to them to discover to what a large extent the temper and methods of scientific inquiry have been brought into the investigation of this most important bio-social problem. In England and in several continental countries societies have been founded, mainly under medical auspices, for the special study of alcoholism, and much valuable work has been recorded in the journals published by these bodies. The *British Journal of Inebriety*, which is the organ of the Society for the Study of Inebriety, has done good service in this way, as has also the quarterly journal issued by the sister society in the United States. In Germany and Switzerland, where the temperance movement has always had a stronger scientific inspiration, much attention has been given to investigations concerning the physiological action of alcohol; and many of the leading authorities in the scientific world of Germany are to be found amongst the contributors to the special journals devoted to the study of alcoholism, such as the *Internationale Monatsschrift zur Erforschung des Alkoholismus* and the quarterly publications, *Der Alkoholismus* and *Die Alkoholfrage*. The medical and social aspects of intemperance also receive very full consideration in other scientific periodicals. To be useful to the students, all this voluminous and scattered literature needs to be classified and sifted, and this is one of the functions which has been undertaken by the recently formed "Bureau International contre l'Alcoolisme," which owes its origin to the zeal and energy of Professor R. Hercod. These evidences of a genuinely scientific spirit in the study of this question will be welcomed the more cordially because they contrast so strongly with the fanatical temper which up to recently was the characteristic of a good many temperance reformers.

Man.—The June number of *Man* describes some recent finds of ancient flint implements, and contains a report of an interview between the Prime Minister and a deputation which urged the necessity of establishing an Imperial Bureau of Anthropology within the Royal Anthropological Institute. At this interview, which took place on March 11th, Professor William Ridgeway, in explaining the object of the deputation, said that not only would some knowledge of anthropology be valuable to administrators in the Indian, colonial, and consular services, but there was evidence of its being a factor in commercial success. Mr. Asquith, in his reply, said that tuition in anthropology must be given by the universities, and there was no present prospect of the Government giving financial assistance. We commented on this matter in THE LANCET of April 10th, p. 1055, and adduced arguments showing the value of such a bureau.

Caledonian Medical Journal.—In the opening article of the July number of the *Caledonian Medical Journal* Colonel Kenneth Macleod, I.M.S. (retired), narrates some reminiscences of his connexion with the Durham County Asylum at Sedgefield before entering for the Indian medical examination at Netley. He says that he now looks back on his period of service in the asylum with very kindly thoughts. Dr. A. C. Miller of Fort William contributes a long paper on the medical inspection of school children. Dr. William Stewart of Wiveliscombe, Somersetshire, writes on birds in myth and folklore. In the editorial paragraphs it is announced that the annual meeting of the Caledonian Medical Society will be held at Lancaster on Sept. 17th under the presidentship of Dr. David Blair. The Society offers a prize of £35 for an essay based on the examination of certain ancient Gaelic medical MSS., Scottish or Irish.

Journal of Laryngology, Rhinology, and Otology. Edited by Dr. J. MACINTYRE, M.B.Glasg., F.R.S.E., and Others. June, 1909. London: Adlard and Sons. Price 2*s*.—This number contains a paper by Dr. A. B. Kelly on Some Experiences in Direct Examination of the Larynx, Trachea, and Œsophagus, which is very well worthy of study. The rest of the number is made up of societies' papers and reports, with a few abstracts.

MEDICINE AND THE LAW.

Criminal Procedure where Prisoners are Alleged to be Insane.

IN an address delivered recently before the Legal and Literary Society of Perth Dr. A. R. Urquhart discussed the question of what should rightly be the procedure in criminal cases in which there is a doubt as to the sanity of a person charged with a crime. We gather from the pamphlet[1] which has reached us containing Dr. Urquhart's address, that in Scotland it has been questioned whether it is strictly logical to distinguish between those accused persons whose insanity is obvious, and whom it would clearly be cruel and unjust to try in open court, and those whose mental condition is more doubtful, or with regard to whom there is a disputed question of temporary dementia, possibly claimed to have existed only at the time of the perpetration of the alleged crime. Those who desire to be strictly logical apparently would have the question, "Is the prisoner sane or insane?" determined by a simple affirmative or negative answer before putting him upon his trial, on the ground that a man mentally deranged suffers from an impairment of the mind which prevents him from conducting or directing his own defence satisfactorily. He should, they say, if insane, be treated as such at once without being submitted to trial as a criminal, the matter of whether he did a certain act being allowed to stand over. Others, again, almost equally logical, urge that, be the man sane or insane, the doubt whether he did an unlawful act should not be allowed to hang over his head, but should be elucidated and set at rest. To some extent the procedure in Scotland seems to differ from that in England, tending to the raising and settling of the question of sanity upon the point of competency to plead. In England we are inclined to think that lawyers will consider the procedure now obtaining to be on the whole satisfactory from a practical point of view, and that medical men will be in accord with them as to the manner in which evidence is given and received as to the prisoner's sanity upon the trial which determines his guilt. That is to say, if the prisoner's sanity is to be adjudicated on by jurors after listening to abstruse and possibly contradictory medical testimony before judges who differ from one another in their treatment of the question of criminal responsibility, then that issue is best fought out with the whole of the facts laid once and for all before the tribunal. The two courses open have been referred to above. When a true bill has been found against a prisoner and he is put in the dock to plead, he may be so patently incapable of understanding the proceedings against him that it would be a scandal to let him remain before the court and be tried. In that case an Act of Parliament provides for the point being decided at once by the jury, and in practice there is seldom any dispute with regard to it, although Dr. Urquhart refers to a Scotch case in which the prisoner was found insane as a preliminary, on the application of the prosecuting counsel, in spite of the fact that those defending him were unwilling that this issue should be raised. On the other hand, there are degrees of insanity, and a man may have committed an unlawful act, who, apart from that incident, lived more or less the life that other men live without his neighbours indulging in any special criticism of his mental capacity. If such a man is indicted for a serious offence, possibly for taking the life of another, he himself or his friends on his behalf are often extremely anxious that he should be spared the fate of a criminal, although the prosecution may assert with tenacity that he is sane and deserves to be punished. The determination of the question thus put in issue may, or, indeed, must in most instances, involve the whole of the evidence as to the committal of an act, claimed possibly as a single example of wrong-doing, and as the result of a brief period of temporary derangement. Evidence on these occasions is gone into which is usually unnecessary where the question of fitness to be tried is raised, and it seems to us that the two classes of case must almost necessarily continue, if for no other reason, as a matter of practical convenience. If the issue of sanity at the time of the committal of the act had to be fought out at the initial stage in a doubtful case upon the whole of the evidence, and if the prisoner's mental condition were then found to be sound, obviously he could not be denied the right to plead "Not guilty." Thereupon the whole of the evidence would have to be gone into again upon the question whether, in fact, he committed the act alleged. We need hardly say that after the prisoner has pleaded the prosecution has to prove the case against him, and that he is presumed then to be sane until the contrary is established by evidence. We do not express the opinion that the ascertaining of the mental condition of the accused is conducted in the best manner possible in our criminal courts, or after the prisoner has passed from court to prison; that, however, is not the topic discussed in the address of Dr. Urquhart to which we have referred.

THE UNIVERSITY OF LIVERPOOL.—Professor Harvey Cushing will deliver the fifth Mitchell Banks lecture on Recent Observations on the Pathology and Surgical Treatment of Intracranial Tumour on Wednesday, August 4th, at 4 P.M., at the University of Liverpool.

THE NATIONAL SOCIETY FOR EPILEPTICS: THE CHALFONT COLONY, BUCKS.—The sixteenth annual meeting of the governors of this society was held on July 19th, at the London offices, Denison House, Westminster, Mr. E. Montefiore Micholls being in the chair. He said that the extension of the Chalfont Colony, which had been so rapid in previous years, had continued without abatement during the past 12 months, a new home for 26 epileptic women having been opened in the middle of 1908, while about the same time two homes for epileptic children were commenced which had now been completed, and were to be open in the coming autumn. One of these homes was for boys and one for girls, and there was in either case accommodation for 24 patients. Each of the three buildings referred to had cost about £3500, and the entire amount had in every instance been provided through the generosity of an individual donor, the women's home having been built at the cost of Mr. Frederick Greene, the boys' home at that of the late Mr. C. A. Tate, and the girls' home at that of Mr. H. Woolcott Thompson. The reports of the executive committee and honorary medical staff for the year 1908 were received and adopted. From these reports it appears that the colony has now accommodation for 224 adult patients, but in view of the fact that there are estimated to be at least 40,000 epileptics in this country, of whom a considerable proportion would be suitable cases for treatment at Chalfont, it is obvious that the accommodation is still quite inadequate, and the committee points to the need for additional homes for men as especially urgent in view of the long period—amounting to more than two years—that male applicants have now to wait for admission, during which time the disease becomes confirmed and aggravated and the hopes of cure destroyed or diminished.

---

[1] The Present Law of Procedure in Medico-Legal Cases in which Insanity is an Element. By A. R. Urquhart. Edinburgh: William Green and Sons. 1909. Pp. 18.

Picard Island, which is situated about 750 miles south-west of Mahé, the chief island of the Seychelles, and cases of the benign tertian type, with a few isolated quotidian, continued to occur up to the end of August—that is, for a period of about five months—during which time practically all the labourers in the settlement had been attacked, but without any fatal results. Owing to the great distance from the headquarters of the Government of the colony and the scanty means of communication, investigation of the epidemic by a member of the medical staff did not take place till mid-September, when Dr. M. S. Power arrived on the scene. He was able at once, by microscopic examination of the blood of some of the patients who were still ill, to confirm the diagnosis of malaria. The worst cases were sent off by ship to Mahé for hospital treatment, and quinine was systematically administered to the remainder, with the result that the epidemic soon subsided. The outbreak had begun soon after the arrival of a vessel from Manhigo, a French island off Madagascar, where malaria was known to be prevalent. Some of the labourers landed from this ship were at the time suffering from malaria, and within a month the disease had spread to the other workers in the settlement. Careful search was made by Dr. Power on his arrival for anophelines, but without success, this failure being attributed at the time to the fact that the season was unfavourable, mosquitoes being comparatively scarce during the south-east monsoon. The larvæ of culex and stegomyia were, however, found. Further search for anophelines was carried out by another expert during and after the rainy season, also without success, although the investigation lasted some four or five months. It was therefore concluded that there were no anophelines in Picard Island. The absence of these mosquitoes from the islands of the Seychelles group had already been remarked upon by previous investigators, and it was well recognised that malaria was unknown in the islands except in the form of imported cases from Madagascar, Mauritius, or Zanzibar; none of these instances had ever, so far as is known, given rise to fresh cases. A statement, however, is made by the Governor in one of his despatches, but to which none of the medical officers allude, that he has been informed that in the Aldabra group a fever closely allied to malaria has always existed. Assuming, then, that at Picard Island competent experts had failed to find anophelines, it becomes necessary to seek some explanation as to how malaria could have become epidemic in the absence of these transmitting agents. Up to the present the anopheline is the only kind of mosquito which has been proved to be an efficient host for the malaria parasite, though one eminent authority says that in view of the large number of species of mosquito existing in one or another part of the world it would be rash to assert positively that the anophelines are the only mosquitoes which transmit malaria. It is possible to conceive that other species, such as the culex or stegomyia, which were present on Picard Island might in certain circumstances be able for a short time to aid in spreading the disease, though not acting as hosts for the malaria parasite. A mosquito disturbed while biting a malaria patient might immediately afterwards bite a healthy man and transfer blood containing parasites from one to the other. It is believed that something like this occurs in sleeping sickness, the transmitter of which is the Glossina palpalis. But certain other tsetse-flies, the G. morsitans, for example, although unable to act as hosts for the sleeping sickness parasite, do in certain circumstances, such as interrupted feeding, actually convey the disease from the sick to the healthy. But the transmission of malaria in this way could only be on a small scale, though the conditions usually found in labour camps in the tropics are favourable to the spread of disease by mosquitoes.

A more probable explanation, however, may be found in the fact that anophelines occasionally are able to board vessels in infected ports and to travel considerable distances. In the present instance the ship which arrived at Picard Island carried some persons already suffering from malaria, so that it is possible that even if the anophelines were not at first infected they had opportunity during the voyage to become infected. On the arrival of the ship the anophelines would go ashore and there find ample opportunity for biting and infecting fresh subjects. It is possible, too, that the conditions at Picard Island were not favourable to the multiplication of the anophelines, or that their natural enemies, being in force, waged war upon them so that they were gradually thinned out and had ultimately disappeared by the time that Dr. Power commenced his investigations. It is unfortunate that the search for anophelines was, for unavoidable reasons, so long postponed. In the circumstances, and considering the evidence available, we think it would not be safe to say positively that malaria spread in Picard Island without the agency of anophelines. Perhaps further information may still be forthcoming to throw more light on this interesting and important question.

Moral Instruction and Training in Schools.

The question of education is mainly of importance to the medical profession in three respects: (1) physical training; (2) the diseases and defects incidental to childhood; and (3) the prevention of future pathological developments, especially in the direction of nervous disorders. It is recognised that for the complete development of the individual, physical training is of extreme importance, not only as regards its effect upon the growth of the body, but also its beneficial reaction upon the development of the intellect and character. The primary schools are gradually replacing the old Swedish exercises by a modified system more suited to the British temperament than the true Swedish system, which has no apparatus or music. At the present time medical officers of considerable ability are being appointed to inspect the various schools with a view to ascertain the health and physical status of the children. It is expected that they will soon supply important data upon which action can be taken to prevent the physical and mental deterioration which some maintain that the nation is undergoing. The extent of the deterioration has been exaggerated, general inferences having been drawn from abnormal conditions, but tuberculosis is a terrible scourge to the race, and vast benefit will follow in this country upon an inspection of our school children which should discover many chronic diseases, such as tubercle, so that they may be checked in the early stages before irreparable injury has been done.

Perhaps the most important rôle of the physician will lie in his ability to prevent future disaster to the child by the early inculcation of a sound hygiene in all departments of life. Teacher and physician must work hand-in-hand for the prevention of future disease, especially of nervous disease, that shadow which follows civilisation. In another column we draw attention to the International Inquiry held last autumn in London on Moral Instruction and Training in Schools. All the educational authorities (British, Colonial, European, American, and Japanese) agreed that the question of moral training is the heart of the modern educational problem; without it, education is a peril. The weakening of the older religious beliefs, together with the rapid growth of science in directions which appear to contradict much dogmatic religion, have left the young generation without an anchor, without any definite and whole-hearted purpose for the guidance of daily life. Education which is concerned only with the training of the intellect fails in its highest goal, the formation of character, and the recognition of this fact has already in some countries led to the compulsory training of the teacher in the essentials of the psychology of childhood. The older methods of education neglected to train the child to make full use of his senses. Before abstract intellectual and literary work is undertaken the child should have begun to observe with eyes and ears, to study nature without the medium of books, and to employ his hands. The corresponding parts of the brain develop without the child experiencing any of the irksomeness and pain which in the average human being are associated with the first years of the older educational method, which starts with abstract literary training. Instead, the child of the future will easily and pleasantly acquire habits of observation that will be invaluable to him in adult life. With a similar systematic all-round training throughout school-life he will retain the sensation of well-being and *joyous interest and pride in his knowledge that is naturally* associated with the activity of a harmoniously developed personality. Education is largely concerned, Professor WILLIAM JAMES tells us, with "the organisation of acquired habits of conduct and tendencies to behaviour." By early and systematic training in good habits, based on sound psychology, the individual can be fitted to cope with the trials of the average life. Habits of daily self-denial in little things keep the character strong for the day when State or family duties require self-sacrifice in a great thing. The child can easily be taught to regard with disgust over-indulgence in food or drink. Healthy habits in diet would lead to a marked decrease in the disorders of the alimentary canal to which is attributable so much of the bad temper, gloom, irritability, quarrelling, and other antisocial qualities which attain so great a mastery over the adult population. Certainly the majority of the highly educated hysterical and neurasthenic patients are the victims of a system of education which has neglected the inculcation of self-control, self-denial, and the habit of taking a healthy, kindly interest in everything and everybody. Highly-strung adolescents of both sexes, finding themselves without enough professional or other occupation completely to fill their waking hours, and unable from lack of training to do anything except read, sink into idle dreaming, thence to years of introspection and fretful complaining, or fall a ready prey to the too prevalent disease of "nerves." No healthy child or adult should know the meaning of the word "boredom": if the whole personality has been harmoniously developed such a condition is impossible. Many of these sufferers can be brought back to physical health and mental and moral happiness by simple training in how to make use of their dormant faculties, physical, intellectual, and moral. But training in good habits is not always enough. Unless the good habits are systematised into a definite whole, are made to correspond to a scheme or purpose in life, they are liable to break down at any time under temptation. Men who live lives of strictest rectitude in their own homes have been known to throw aside all codes of morality when sent to sparsely populated or more lax communities, without considering that they are at all to blame. Authorities in the study of religion and philosophy differ as to the ultimate sanction of morality, whether it is based upon prudential and personal, social or religious considerations. Into this question the average child, and even the average adult, does not inquire; for all practical purposes of useful life it is enough to teach the indisputable fact that humanity most reveres and respects that man whose morality is consistent, irrespective of time or place, whose life is lived ever as in the presence of a great ideal.

Teachers should be selected for their moral tone, rather than for their athletic and scholastic attainments. The normal human child will respond to the stimulus of a noble character; hero-worship is natural and productive of good both to the child and the nation when employed as a means of education. The child may in after years forget the facts acquired by memory, but not the facts which appealed to the imagination and aroused the disinterested emotions of wonder and admiration. History bears out the importance of private virtue as the source of national greatness. Mr. LECKY writes: "*If you would form a wise judgment of* the future of a nation observe what qualities count for most in public life. Is character becoming of more or less importance? Are the men who obtain the highest posts in the nation men of whom in private life ...... competent judges speak with respect? Are they of sincere convictions, consistent lives, indisputable integrity?" From the point of view of the physician there is no doubt that the man whose life in every daily act as well as on the rare occasions for great deeds, is lived *sub specie æternitatis*, with single-minded reference to an ideal end, is a healthier and happier human being. In the stress of modern civilisation the man who has no unity in his scheme of life and is racked with doubts, the man who frets over trifles and tries with his disjointed and vague philosophy to solve every little point as it arises, whose only measure or ultimate sanction for action is the impulse of the moment—that man is at the mercy of circumstances, his nervous energy is readily exhausted, and he is liable at any time to fall a victim to hypochondriasis, melancholia, or neurasthenia, if not to vice with its attendant evils. It is time to teach the younger generation the great truth that humanity is being driven on an upward path, that the fortunate man is he who early discovers the fact that the Universe is making for good, and that as a consequence virtue is the easier and happier, not admirable work which is being done by the Metropolitan Water Board in the purification of the London water, and by the Local Government Board and local authorities in preventing as far as possible the pollution of the rivers from which the bulk of the London water is obtained is vital to the existence of the inhabitants of London.

WOUNDS OF THE DIAPHRAGM.

As the knife is little used as a weapon in this country wounds of the diaphragm are seldom seen by the surgeon. In the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of June 27th M. Rabère has reported two cases which present several points of interest. A robust man, aged 29 years, was admitted into hospital an hour after he had been stabbed in the left side of the chest. In the eighth intercostal space and anterior axillary line was a wound three or four centimetres long running obliquely downwards and forwards, from which projected a piece of omentum about ten centimetres long. The patient showed no signs of shock but was excited by alcohol, in which he had been indulging. The respiration was a little panting, but the pulse was strong and regular. The respiratory murmur was weak on the left side, which the patient instinctively immobilised. There were no signs of hæmothorax or of internal hæmorrhage, and no external hæmorrhage or hæmoptysis. The abdomen was supple and showed neither pain nor area of dulness. Under chloroform ten centimetres of the rib below the wound were resected and the underlying pleura was incised. As a result, the omentum, which was strangulated in the wound, was liberated. The omentum formed a guide to the wound in the diaphragm, the upper edge of which wound was seized with forceps and dragged out. This manœuvre tended to prevent the production of pneumothorax. There was no hæmorrhage into the costo-diaphragmatic sinus, which, with the absence of hæmoptysis, indicated that the lung was not wounded. The diaphragmatic wound was slightly enlarged in a forward direction and its upper edge was united to the upper edge of the thoracic wound by two catgut sutures. The herniated omentum was resected, the stump was reduced, and the upper abdominal viscera—spleen, transverse colon, and anterior and posterior walls of the stomach—were explored. There were some clots in the vault of the diaphragm. Minute examination showed that the hæmorrhage was due to wound of an artery in the omentum. This artery was ligatured, the clots were removed, the wound in the diaphragm was sutured with catgut, a drainage-tube was inserted between the diaphragm and the chest wall and the external wound was sutured. Recovery was uninterrupted; some serous fluid escaped from the tube for a few days. The patient got up on the twelfth day, when all that could be detected was some pleural friction. In the second case the wound was exactly in the same place as in the previous case, but there were hæmorrhage in gushes during expiration, hæmo-pneumothorax, abundant hæmoptysis, and signs of severe internal hæmorrhage. Thoracotomy was performed, a flap containing portions of the seventh, eighth, and ninth ribs being raised. A wound of the diaphragm was found through which the left angle of the colon had passed. After reduction of the hernia, rapid examination of the spleen and stomach, and suture of the diaphragm, the lung was explored and a long and deep wound was found in it and sutured with catgut. The pleural cavity contained a large quantity of blood, which was evacuated. The flap was replaced and sutured. The patient died soon after the operation. The necropsy showed that there were no other lesions than those found at the operation. Omental hernia is a frequent sign of wound of the diaphragm. Its mechanism is easy to comprehend; during expiration the diaphragm is in contact with the lateral thoracic wall, and the omentum passes through the parietal and diaphragmatic wounds as if they were one. Wound of the diaphragm indicates immediate operation, for in consequence of thoracic aspiration abdominal viscera readily pass into the pleural cavity, become strangulated, and press on the heart and lungs. Another reason is the possibility of wound of the spleen, stomach, intestine, and liver, or large vessels. Some surgeons have operated by the abdominal route. Lenormant has reported eight cases thus treated, with five deaths. But by this method it is difficult to reach the wounded viscera and, above all, to suture the diaphragm, as the stomach and colon always form obstructions. Continental surgeons are almost agreed that the thoracic route is the best. Lenormant has reported 23 cases in which this was followed with three deaths. It has been objected that in this method pneumothorax may be induced. But many surgeons do not consider it of importance; it may sometimes be easily prevented, as in the first case reported above; and it sometimes already exists, as in the second case.

THE RELATIONSHIP OF THE OPTIC NERVE TO THE SPHENOIDAL SINUS.

DURING recent years it has become more and more apparent that inflammation of the optic nerve and of the deeper structures of the orbit is frequently to be traced to a primary infection of the accessory sinuses of the nasal cavity, especially to the deeply placed and imperfectly known sphenoidal sinuses. Unfortunately these spaces are rarely examined in the usual routine of the post-mortem room, but such records as are available indicate that 30 per cent. of all subjects show disease of the accessory sinuses, the sphenoidal being affected in about 15 per cent. Onodi has shown how closely the sphenoidal and posterior ethmoidal cells abut on the optic nerve. In a paper read before the American Academy of Ophthalmology and Otolaryngology, Cleveland, in September, 1908, and now republished in the report of the Laboratories (Medical Department) of the University of Buffalo, Dr. L. M. Francis and Professor J. A. Gibson record a number of observations on the thickness of the bony partition between the optic nerve and sphenoidal sinus. In a series of 60 skulls they found this to measure 1-100th of an inch or less in 20, 1-50th inch or less in 18, 1-25th inch or less in 10, 1-12th inch or *more* in 12. They also mention the close relationship that exists between the sheath of the optic nerve and the lining membrane of the sinus, so that it is not too much to say that the optic nerve, in the majority of human subjects, lies in the wall of the sphenoidal sinus and is liable to become affected in all the diseases of that sinus. Professor Gibson found that the average distance of the sphenoidal sinus from the nasal spine in the skulls he examined (85 in number) was 57 millimetres, and that in 17 per cent. there was a diverticulum of the sinus which extended into the wall of the orbit. Apparently the nasal cavities are of a greater depth in English subjects, for in a series of observations published some time ago by Mr. H. Tilley, the average distance of the sphenoidal sinus from the naso-labial margin is given as 82 millimetres in the male and 76 millimetres in the female subject.

THE REMOVAL OF KING'S COLLEGE HOSPITAL.

ON July 20th the King, in the company of the Queen and of Princess Victoria, gave another proof of the interest which he takes in the welfare of the sick poor by laying the foundation-stone of the new buildings of King's College Hospital which are to be erected by Mr. W. A. Pite, F.R.I.B.A., facing Bessemer-road at Denmark Hill, and which are to form the new home of the charity that has existed for 70 years in the Strand district. A guard of honour was furnished by the University of London contingent of the Officers' Training Corps. The Hon. W. F. D. Smith, M.P., chairman of the committee, and the generous donor of the 12 acres of land on which the new hospital will stand, presented an address to His Majesty, stating that 600 beds will be accommodated in the new building, which will also have the advantage of a people's park of 30 acres adjoining its south side. The approval of the King Edward's Hospital Fund for the removal scheme had been shown by a gift of £27,000. His Majesty, replying in his usual felicitous terms, fully endorsed the action of the Fund associated with his name. "Your committee's decision to abandon the old building," he said, "and to remove the scene of your labours to a poorer and more populous district, where the need for a hospital was great and the field for its work wide, was a bold step, but I believe it was a wise and right one, and I congratulate the medical and nursing staff on the great opportunity thus given them for increased usefulness. The generous response made to the committee's appeal for funds shows how their decision has been appreciated by the public." He recalled with gratitude the past work of the hospital and mentioned with honour the great career of Lord Lister within its walls, "who, in introducing the antiseptic methods in surgery, rendered an inestimable service to England and to all mankind." After commending the financial needs of the hospital to the benevolent, His Majesty concluded his speech with these words: "I assure you of my continued interest in your hospital and of the sympathy with which I shall watch its future progress. I cannot doubt that the blessing of Almighty God will attend the work to be done by it in its new home." The King then laid the foundation-stone and the Benediction was pronounced by the Bishop of Southwark, the ceremony concluding with a number of presentations to His Majesty. The committee of King's College Hospital is to be warmly congratulated on having passed such an important milestone on the path of its long and anxious labours, and we cannot doubt of the wisdom of the steps it has taken. The removal of the hospital will not only be the means of rendering its benefits easily accessible to a far larger poor population than it serves conveniently at present, but the extension of its beds will form a noteworthy addition to the already unrivalled field of clinical opportunities at the disposal of the London student. This educational function of a general hospital had always been kept in mind by the governing body of King's, which, indeed, was founded by the council of King's College with that end chiefly in view, as witness the following extract from the council's minute book for 1839: "The council of King's College, finding that hospital practice in connexion with and in the vicinity of the said college was indispensable for the complete education of its medical students, did, in the year 1839, take measures for the formation, in the parish of St. Clement Danes, in the county of Middlesex, of a public hospital for the relief of poor, sick, and infirm persons, to be supported by voluntary contributions, and to which the students of medicine and surgery belonging to the said college might, under proper regulations, for ever have access." These objects have not been forgotten, and those who support liberally the appeal for a further sum of £75,000 which the committee is now making will not only assist a worthy charity but will be forwarding the interests of an important school of medicine of the University of London.

ASYLUM OFFICERS' SUPERANNUATION BILL.

THE Asylum Officers' Superannuation Bill has passed its second reading in the House of Commons and is now before a Select Committee. In the present condition of public business in the House it seems little likely that the Bill will become law, and only too probable that this useful reform will be indefinitely postponed. The object of the Bill is to impose an obligation upon asylum authorities to grant superannuation allowances to their officers and servants upon a fixed scale. At present the granting of such allowances is discretionary, and though widely practised it is felt by those concerned that it would distinctly improve the status of asylum workers and attract the right sort of individual to the service of the insane if the grants were not at discretion but of statutory obligation. By the provisions of the Bill the amounts of the grants will differ according to the nature of the employment and the period of approved service, while provision is made for contributions from officers and servants. The supporters of the Bill are of opinion that no additional burden will be put upon the rates, and indeed that the system of contribution will materially reduce the expenditure upon pensions. The Bill was referred to at the eleventh annual meeting of the Asylum Workers' Association which was held on July 14th, and at which Sir William Collins, who was in the chair, was re-elected President of the Association. In moving the adoption of the report he expressed himself strongly in favour of the Bill, which was supported even more strongly by his seconder, Mr. C. Roberts, M.P., an honorary Commissioner in Lunacy, who said that the whole of the Lunacy Commission was in favour of its adoption. A Bill that at once confers a boon upon a highly deserving class and is likely to reduce the rates appears to us one worthy of high commendation, and we hope that a few minutes of the public time may be spared to effect the passage of so excellent a measure.

A CERTIFICATE OF THE CAUSE OF DEATH FOLLOWED BY AN INQUEST.

A DISCUSSION of an unusual kind has taken place at Newcastle-upon-Tyne between a medical practitioner and a coroner, and has been accorded publicity by the local newspapers. Dr. F. C. Coley was consulted by a man, aged 70 years, a builder by trade, who described his symptoms to him and submitted himself to examination. Dr. Coley saw his patient twice during a period of 12 months, the last occasion being on May 28th, and formed the opinion that he had suffered from mild attacks of angina pectoris. On June 28th the relatives informed the medical man that his patient had been found dead in his bed, adding particulars to the effect that he had been fatigued on the previous day and had had to hurry to catch a train. In these circumstances Dr. Coley gave a certificate assigning angina pectoris as the cause of death. The attention of the coroner was called to the case, and he decided to hold an inquest, being apparently of the opinion that owing to the interval of a month which had elapsed since the last visit to the medical man a certificate ought not to have been granted. At the inquest Dr. W. F. Wilson, who had made a post-mortem examination, expressed the opinion that death was due to "heart failure brought on by heart disease," and the jury returned a verdict of "Death from heart failure," further expressing the opinion that Dr. Coley was not justified in giving a certificate of the cause of death in the circumstances. It is hardly necessary to point out that Dr. Coley was perfectly within his rights in giving a certificate if the conditions described to him under which his patient died coincided with the state of his health observed a month before, and that the blame which the coroner allowed the jury to impute was quite undeserved. The case is unusual because the far more frequent cause of complaint against medical men arises out of the withholding of certificates which cannot conscientiously be granted, but which in the opinion of the coroner or the jury would save the necessity of an inquest.

THE METROPOLITAN WATER-SUPPLY.

REPORT ON CHEMICAL AND BACTERIOLOGICAL EXAMINATIONS FOR THE YEAR ENDING MARCH 31ST, 1909.

AN exhaustive report on the results of the chemical and bacteriological examination of the London waters for the 12 months ending March 31st, 1909, has been drawn up by Dr. A. C. Houston, director of water examination, Metropolitan Water Board, and was presented at a meeting of the Board on July 2nd.

The report is a very detailed one, and contains a great number of carefully tabulated analyses in addition to an admirable summary of these results and carefully drawn-up conclusions. The following is an abstract of the more important points contained in it.

I.—*Meteorological Notes.*

Meteorological notes, by Dr. H. R. Mill, are recorded, and the relationship of the rainfall and general meteorological conditions of the different months in the year to the average daily flow of the river Thames and the bacteriological condition of the raw Thames water is illustrated by a table drawn up by Dr. Houston. March and April were the two months of highest rainfall, and they were the months in which the number of bacteria per cubic centimetre of raw Thames water far exceeded the figures for the other months. Dr. Houston points out that meteorological records are indispensable not only for calculating the potential supply of water but also on account of the important light they throw on the seasonable variations in the physical, chemical, and bacteriological qualities of the water. He makes the very important statement that in his view unfavourable meteorological conditions should not afford justification for delivery into supply of imperfectly purified water.

II.—*Statistics of Supply.*

Dr. Houston adds a note of caution to the way in which these figures should be interpreted. There must be adequate storage capacity in the reservoirs both before and after filtration. If there is inadequate service reservoir capacity he points out the great liability there may be of too rapid filtration which, of course, involves the danger of imperfect bacteriological purification. Also it is pointed out that in considering the rate of filtration one must look not to the total rate for a number of beds but to the rate of filtration of each individual bed. One filter bed in which the rate of filtration was too rapid might lead to the pollution of the water from a number of other beds which were working satisfactorily at a proper rate.

III.—*Effect of Storage.*

A very interesting part of the report is the important light thrown on the enormous value of storage of water before filtration. It is stated that in relation to danger to health over-storage is believed to be impossible, and that it is desirable to store a water before filtration for as long a time as it is economically possible. The storage of water may lead to inconvenience in filtration from the overgrowth of algæ and other vegetable growths, since the beds become blocked by the vegetable blanket which forms on the surface of the sand in the filters. This difficulty has been overcome in various ways; thus in 1908 the addition of minute amounts of copper sulphate had a great retarding effect on vegetable growth in the water stored. Also, it has been found that the mixture of a certain amount of unstored river water with stored water prolonged the life of a filter-bed to a great extent. Dr. Houston gives 20 conclusions as to storage, all of which go to show the great value of this process in the purification of water. One of these is very striking: "The use of stored water goes far to wipe out the gravity of the charge that the chief sources of London's water-supply are from sewage-polluted rivers."

IV.—*Research Work.*

Dr. Houston rightly insists that routine work systematically conducted in the Board's laboratories is very important research. During the year special researches have been carried out thus: A first research report has been published showing that if living typhoid bacilli are kept in raw Thames, Lea, and New River water 99·9 per cent. perish within one week. This result proves that the advantages accruing from even a few days' storage are so great that there is no justification for the use for filtration purposes of raw unstored river water. A second research report involved a special search for the typhoid bacillus in samples (collected weekly) of raw Thames, Lea, and New River water. These results were negative, but Dr. Houston adds that negative results of this kind cannot be regarded as absolutely conclusive. A special research report on the Vitality of the Cholera Vibrio in Raw River Water is published and is dealt with below.

V.—*Bacteriological Results.*

Raw water.—The averages for the 12 months were as follows:—Raw Thames water, 2558 microbes per cubic centimetre: highest 8072, March; lowest 1107, July and February. Raw Lea water, 8794 per cubic centimetre: highest 38,469, March; lowest 1706, November. Raw New River water, 1118 per cubic centimetre: highest 3566, March; lowest 233, April. The worst month in each instance was March. Dr. Houston states that in a gravitation scheme with a superabundant source of supply and huge storage reservoirs the amount abstracted for storage purposes should be inversely proportional to the current impurity of the water. In the circumstances pertaining to the London supply this is only possible in a partial sense, but attention must again be drawn to the fact that the amount of river water abstracted during the months when the river contains an excessive number of bacteria is so large as to emphasise the desirability of passing it through storage reservoirs antecedent to its filtration.

A table is contained in the report showing for the Thames and Lea waters the average number of bacteria per cubic centimetre in the raw water for each month of the year and the average daily quantity of water abstracted for waterworks purposes. The table shows that in the months of March and April where the bacterial figures are very high the abstraction figures by no means follow the desirable rule of being inversely proportional to the bacterial impurity.

Filtered water (including Kent and Lea Valley unfiltered water).—The following statement indicates that the exclusive (i.e., exclusive of samples containing 100 or more microbes per cubic centimetre) figures for the filtered waters were small, and the percentage reduction effected by the processes of subsidence and filtration remarkably good as is shown below:—

—	Thames.	Lea.	New River.
Raw water (microbes per c.c.)	2558	8794	1118
Filtered water (microbes per c.c.)	11·3	18·9	6·1
Percentage reduction (microbes per c.c.)	99·6	99·8	99·4

Too much stress, it is added, must not be laid on percentage reduction of microbes. The worse the raw water, the easier it is to obtain a final filtrate yielding satisfactory results on the basis of percentage purification. The order of merit based on the exclusive figures for the filtered waters is as follows:—

	Average number of microbes per c.c.		Average number of microbes per c.c.
Kent	5·3	West Middlesex	12·3
New River	6·1	Chelsea	14·6
Lambeth	7·0	East London (Thames)...	17·6
Southwark and Vauxhall	9·3	East London (Lea)... ...	18·9
Grand Junction	9·9	Kempton Park	19·7

Tests for Special Organisms.

Bacillus enteritidis sporogenes.—

Raw waters.—40·3; 59·6; 82·6 per cent. of the samples of New River, Thames, and Lea water respectively yielded positive results with 100 cubic centimetres of the water.

Filtered waters.—Only 3 per cent. of the samples of filtered waters yielded positive results with 100 cubic centimetres of water. Dr. Houston points out that negative results do not necessarily imply safety as regards the particular organism examined.

Typical bacillus coli tests.—

Raw water.—The results, judged by this test, were unsatisfactory, having regard to the fact that the rivers Thames and Lea are known to be seriously polluted with sewage and that there is every reason to suppose that the majority of the bacilli coli found in the raw waters are of human excremental origin. The average numbers of typical bacilli coli per cubic centimetre were calculated as follows: river Thames, 15; river Lea, 25; and New River, 1.

Filtered waters.—The following table shows the average number of typical bacilli coli per 1000 cubic centimetres of filtered water:—

	Typical B. coli per 1000 c c of water.
Kempton Park	1
Kent, Chelsea, East London (Lea), New River, Lambeth, Grand Junction	2
West Middlesex, Southwark and Vauxhall	3
East London (Thames)	137
Lea derived water, New River derived water	2
Thames derived waters	3
All London waters	2

Dr. Houston adds that without pushing these figures too far it may be said that, taking the London waters as a whole, the improvement effected by subsidence and filtration was 6850 times.

VI.—*Chemical Results.*

The results of periodical analyses of the various raw and filtered waters are carefully tabulated for each month. The purifying effect of subsidence and filtration is well shown by the figures given for the albuminoid nitrogen test and for the oxygen absorbed from permanganate. In each case the figures for the filtered waters are less than half those of the raw waters. The differences between the chemical analyses of raw and filtered waters are, of course, much less striking than the remarkable differences between the bacterial figures given for these two classes of water, the reason being that the chemical impurities are in solution.

Dr. Houston draws the following conclusions from the results of the various investigations made during the year:—

Conclusions.

Raw Water.

1. The unsatisfactory quality of the raw waters, particularly during the winter months.

2. The importance of judicious selection of raw water for waterworks purposes.

3. The *doubt* whether the raw waters, even during the best months of the year, are sufficiently free from impurities to be filtered without antecedent storage.

4. The importance of possessing as full knowledge as possible of the multiple pollutions of the rivers Thames and Lea.

Storage.

uate, duration of storage in

passive storage," and the
e epidemiological point of
view.

Filtration.

7. The unequal, and in some cases too rapid, rate of filtration at the different works

Service Reservoirs

8. The small size of the service reservoirs leading in some cases to variable rates of filtration during the 24 hours.

Filtered Water.

9. The variable and in some cases not altogether satisfactory quality of the water as delivered to the consumers from the different works, and the general deterioration in the results during the winter months of the year.

10. The remarkable percentage improvement in the quality of the

extreme undesirability of ever using unstored raw river water for filtration purposes.

14. The results of the examination of river water antecedent and subsequent to storage, carried out during the last 20 months, clearly

Fourth Report on Research Work.

This report deals with the vitality of the cholera vibrio in artificially infected samples of raw Thames, Lea, and New River water, with special reference to the question of storage. Dr. Houston states that he is content to abide by the general view held that cholera is liable to be water-borne and that Koch's cholera vibrio is the microbe which conveys the disease. He mentions the cholera epidemic which was raging in Russia in 1908 and in the present year, and alludes to the possibility of cholera being conveyed to this country from Russia or India, although there is a first line of defence owing to the vigilance of the Local Government Board, port sanitary authorities, rivers boards, and medical officers of health, which may prevent contamination of our water-supplies. Dr. Houston says that the ravages of cholera in the past forbid the belief that our insular position and temperate climate afford us sufficient protection from this disease.

Eighteen experiments were carried out, namely—six with raw Thames water collected at Hampton, six with raw Lea water collected at Ponder's End, and six with raw New River water collected at Hornsey. These waters were inoculated with large numbers of living cholera vibrios from artificial cultures, and the samples were tested at weekly intervals by various methods and in different media for the cholera vibrios. In every case at the end of one week the percentage reduction of microbes present was over 99·9 per cent., and in every case at the end of three weeks it was found impossible to isolate any cholera organisms from 100 cubic centimetres of the infected sample.

Dr. Houston very fairly points out that he experimented with vibrios which had been grown on an artificial medium and not with organisms taken directly from the excreta of a cholera patient; also that the experiments were necessarily conducted in a laboratory, the conditions being different from those which would obtain if cholera vibrios were present in a storage reservoir. He says that it is always dangerous to argue from the particular to the general and to deduce from the results of artificial laboratory experiments the results likely to occur in natural conditions. He adds that the moderate character of his conclusions will be accepted as evidence of the careful manner in which he has sought to guard against errors of this kind.

Division 2 of the report is concerned with the detailed manner in which Dr. Houston devised methods by which he could with certainty identify true cholera vibrios, and he shows that by means of the technique which he specially worked out he was able to isolate cholera organisms from water if present in amounts as small as one per cubic centimetre. The following conclusions were arrived at:—

1. Cholera vibrios die very rapidly in *raw* Thames, Lea, and New River water as the result of storage in the laboratory. At least 99·9 per cent. perished within one week, and in none of the experiments could

any cholera vibrios (recognisable as such) be found even in 100 cubic centimetres of water three weeks after its infection. In more than half the experiments the results were negative by the second week (see Division 1).

2. The isolation of cholera vibrios from *artificially* infected *raw* river water presents no insuperable difficulties even when the number artificially added is very [illegible] relatively to the bacteria normally present in [illegible]

3. On the other ha[illegible] ul study) to be mistaken for true cholera vibrios were not found in comparable, but non-infected, river water samples examined under precisely similar conditions (see Division 2).

4. All that I have said in the past as regards the advantages of storing river water from the point of view of typhoid fever applies to cholera, and the time required to ensure reasonable safety in the former case is, on the basis of these experiments, more than sufficient in the latter.

5. There are many circumstances which separately, and still more in conjunction, tend to safeguard this country from a cholera invasion. But no responsible authority can regard a cholera visitation as impossible, and, if it is possible, the part played by impure water in the past in spreading the disease should not be forgotten. Fortunately, even an initially impure water can, by adequate storage and efficient filtration, be brought into a condition of reasonable, if not absolute, safety.

6. In the particular case of the metropolitan water-supply there remain four reassuring circumstances even in the extreme (and, it is to be hoped, highly improbable) event of the raw sources of water-supply ever becoming infected with cholera. Firstly, the cholera vibrios, even if they were present in very few numbers, could be detected in the river water by appropriate tests (see Division 2). Secondly, adequate storage of the river water would eliminate the great majority, if not all, of them (see Division 1). Thirdly, the final filtration process, if efficient, would be an additional safeguard of proved value. Lastly, as the result of my experience at Lincoln, I should not be unprepared *in any emergency* to face the responsibility of sterilising the water-supply, if this was thought to be desirable, and so rendering it absolutely safe for drinking purposes. The existence of large storage reservoirs renders such a project quite feasible as a temporary expedient.

7. Although by no means defending the choice of an impure river water for waterworks purposes, the facts revealed in this report appear none the less to be of a reassuring character and to form another link in the chain of evidence which I have sought to establish—namely, that by adequately storing the *raw* impure river waters which constitute the chief sources of London's water-supply, antecedent to their filtration, the safety of the metropolis as regards water-borne epidemic disease (apart from the possibility of accidental infection at the works, or subsequently in the pipes) is almost, if not quite assured.

REPORT OF THE DEPARTMENTAL COMMITTEE ON THE WEST AFRICAN MEDICAL STAFF.

FOR some time there has been dissatisfaction in the West African Medical Staff, more especially in the junior ranks, as regards their prospects in the service, and owing to this and other circumstances candidates of a high class have applied for posts on the staff in insufficient numbers. The Secretary of State for the Colonies therefore decided in 1908 to appoint a Departmental Committee to inquire into the duties, organisation, emoluments, and selection of officers for this service. The Committee, which began its labours in November of last year, consisted of six members, three of whom, including the chairman, Mr. H. I. Read, C.M.G., were officials of the Colonial Office, and three were medical men—viz., Dr. Theodore Thomson, C.M.G., of the Local Government Board; Mr. W. H. Langley, C.M.G., principal medical officer, Gold Coast; and Dr. J. K. Fowler, late Dean of the Medical Faculty, University of London, and senior physician to Middlesex Hospital. The Committee held 13 sittings, at which a number of witnesses were heard, including Sir Patrick Manson, K.C.M.G., medical adviser to the Colonial Office; Sir A. Keogh, K.C.B., Director-General Army Medical Department; Surgeon-General A. M. Branfoot, I.M.S.; Major Ronald Ross, C.B., F.R.S., professor of tropical medicine, University of Liverpool; Professor W. J. R. Simpson, C.M.G., of King's College and the London School of Tropical Medicine; Lieutenant-Colonel J. Will, R.A.M.C., formerly principal medical officer, East Africa Protectorate, and others, some of whom were past or present officers of the West African Medical Staff. The report of the Committee has now been published. It comprises some 24 printed folio pages and contains a number of recommendations, in the forefront of which prominence is given to the creation of an advisory committee the functions of which should extend to East as well as to West Africa. It is urged that this new body would enable the Colonial Office to maintain closer relations with the medical profession and with medical science, and would be capable of offering expert advice to the Secretary of State if he so desired, it on questions connected with tropical medicine and hygiene, including schemes for drainage and water-supply, plans for preventing and stamping out epidemic disease, bacteriological work, &c. It would also be able to advise as to selection of suitable candidates for appointments in the East and West African Medical Staffs, and as to filling up vacancies by promotion in the senior ranks of these services; it would further advise as to courses of study which medical officers should be called upon to undertake before promotion to the higher grade. This advisory committee, it is recommended, should consist of six members, two of whom should be Colonial Office officials representing East and West Africa, one of them acting as chairman; the remaining four members should severally represent tropical medical research, tropical hygiene, medical science and practice, and general hygiene. It is also recommended that if there should be available a retired medical officer of senior rank of the West African Medical Staff able to give the necessary attendance he should be appointed an additional member of the committee.

Duties and organisation.—While of opinion that it is not possible to make a complete distinction between the medical and sanitary duties of the staff, the Departmental Committee thinks that in the large towns such as Lagos, Accra, and Freetown sanitary work may be assigned to special officers who should give their whole time to such duties and who should hold a diploma in public health or an equivalent qualification. In out-stations, where the majority of medical officers reside, these officials must also act as part-time sanitary officers. The Committee advocates, in addition, the appointment of a limited number of the senior officers to devote themselves to the study of sanitation in West Africa, who should make tours of inspection both in coast towns and out-stations, making reports and if necessary recommendations to the principal medical officer. The reports would be forwarded by the latter to the Governor *in extenso*, with such observations and criticisms as might be desirable. The Committee does not favour the creation of boards of health to advise the local governments on questions of health and sanitation. It does not advise the appointment under prevailing conditions of a director-general of the West African Medical Staff; nor does it think that the appointment of an inspector-general is at present warranted. With regard to existing relations of the staff to the executive government and its officers, there appears to have been friction in the past, due, to some extent, to the view held by certain administrative officers that the medical department is subordinate to them and liable to be called upon for any duty at the discretion of these administrative officers. It seems strange to hear that in West Africa medical officers are regarded as having the smallest amount of work to perform, and that therefore they may be called upon in their so-called leisure hours to undertake duties outside their profession without any additional remuneration. There seems, too, to have been a practice of some administrative officers entering, for example, in the hospital visitors' book criticisms which were deeply resented by the medical officers. The Committee is strongly of opinion that the medical staff should be as far as possible restricted to their professional duties. It is pointed out that if these officers are employed in other work during their leisure hours they can take no share in the study and observation of clinical cases, original research, or other scientific work. It is recommended that the principal medical officer of each colony should be *ex officio* a member of the Executive Council and also of the Legislative Council.

Emoluments.—The present scale of pay for medical officers joining the staff is £400 per annum, rising by increments of £20 to £500. Till now the prospect of attaining a higher salary than this was to the majority exceedingly unfavourable. There are at present 167 officers of all ranks in the service, of whom only 21 are in receipt of a salary of £600 or more. Promotion is extremely slow, and naturally this condition of affairs has given rise to great discontent. To deal with this the Committee recommends the creation of a new grade to be termed "first-class medical officers," with a salary commencing at £500, rising by annual increments of £25 to £600. Such of the medical officers who have completed five years' service and who may be reported upon favourably to the Government by the principal medical officer are to be recommended for promotion to the rank of first-class medical officer, subject to the condition that such officer when next on leave will attend a course of study of not less than three months' duration, and subject to his obtaining a certificate of satisfactory attendance, diligence, and proficiency. It is believed that these conditions will, on the one hand, prevent the promotion of unsatisfactory officers, and will, on the other, ensure that deserving officers will not be kept indefinitely serving at a maximum salary of £500, owing to lack of opportunities for promotion. Senior medical officers now receive £600, rising by £20 annually to £700; it is recommended that the increments be £25 instead of £20, and that officers of this grade, as well as those of the higher rank, should receive "duty pay." A recommendation is also made that a new grade of senior medical officer should be created to be named "first-class senior medical officer," with a salary of £700, rising by £25 annually to £800. Senior sanitary officers are to rank as first-class senior medical officers and to draw the same pay; and sanitary officers will rank as senior medical officers, with the pay attached to that grade. Further, deputy principal medical officers' pay is to be increased from £700 to £800, rising by increments of £25 to £900, with duty pay of £160. All principal medical officers should receive duty pay at the rate of £160 a year. No alteration is to be made in the special scale of gratuities to those officers retiring from the staff after nine or 12 years' service; nor is any alteration in the scale of pensions suggested. The question of private practice is discussed; there is none, however, to be had at most stations, and, as a rule, such practice where it is obtainable is allocated to the senior members of the staff. In West Africa difficulties have arisen as to what constitutes private practice and as to fees. The Committee recommends that when any difficulty as to these arises it should be referred in the first instance to the principal medical officer of the colony; and if his decision is disputed, that the matter should be submitted to the Governor for final settlement.

Study-leave is next considered, and it is recommended when the study is undertaken for promotion to the rank of first-class medical officer, that on production of the required certificates the fees should be paid for the officer, as well as the usual railway fares and lodging allowances. In other cases where special courses of study are taken in the interests of the service the same allowances and fees mentioned above should be paid. With a view to fill the sanitary posts already referred to, the Committee urges that medical officers with any aptitude for sanitary work should be encouraged to take the Diploma in Public Health or an equivalent qualification. As regards facilities for scientific research, it is recommended that apart from the Lagos Medical Research Institute already established, other local laboratories in the larger colonies should be provided where research work and routine analyses could be carried out by officers detailed from time to time for the purpose.

Recruitment.—It is hoped that the improved conditions of service recommended by the Departmental Committee will attract in larger numbers candidates of a high class. In the past it has not always been easy for outsiders to obtain information concerning the duties and emoluments of the West African Medical Staff. Vacancies, it is thought, should be made public by advertisement. It is now suggested that there would be advantage in distributing to the principal medical schools of the United Kingdom printed information concerning not only the medical staff but also as to the climate of East and West Africa, exaggerated views as to the unhealthiness of which are held in some quarters; the West Coast of Africa is still regarded by some persons as "the white man's grave." The Committee deprecates the employment of natives of West Africa, or of India, in the West African Medical Staff. There are some other minor points to which considerations of space do not permit us to allude on the present occasion.

Along with the Committee's report is published a despatch by Lord Crewe, dated June 18th, 1909, and addressed to the Governors of the Gambia, Sierra Leone, Gold Coast, Southern Nigeria, and Northern Nigeria, commenting upon the report and some of the recommendations. The Secretary of State on the whole is in agreement with the Committee, but he says there are certain points arising out of the report relating to [illegible] by the Secretary of State, and we see no reason why they should not, many of the causes of dissatisfaction and discontent in the West African Medical Staff will disappear, and the ultimate effects of the improved conditions of service will doubtless attract men [illegible] systematic application, by highly [illegible] fied officers, of the principles of [illegible] and hygiene to West Africa in the future must result in great improvement in the healthiness of these regions, with consequent increase in their material prosperity and economical development.

THE EARLY TREATMENT OF THE INSANE IN THE COUNTY OF LONDON.

THE recommendations of the Royal Commission on the Control and Care of the Feeble-minded have led the asylums committee of the London County Council to suggest the reintroduction next session of the Lunacy Acts Amendment (London) Bill, by which the Council has sought powers to establish receiving houses for the reception of persons mentally afflicted or alleged to be of unsound mind, with the object, if possible, of curing insanity in its early stages.

In a report presented to the Council on July 20th the asylums committee notes with very great satisfaction that [illegible] contains the following statement:—

"We regard it as very important that a free hand should be allowed to committees in dealing with this matter, so that they may be able to utilise many existing agencies for the purpose. We do not consider it at all necessary that in crowded centres of population large and expensive buildings should be erected like the reception blocks of the great county asylums. Separate wards in workhouses or in general hospitals might be used under contract, or existing houses or other buildings adapted. The special advantages of these reception wards for the clinical study of mental disease are so evident that many general hospitals, especially those to which medical schools are attached, would be glad, we think, if they were subsidised, to provide them within their own premises with medical, nursing, and attendant staff complete."

Reviewing the reasons why the establishment of receiving houses is desirable, the asylums committee points out that at present the Council's duty to the lunatic commences with his admission to, and ends with his discharge from, one of the asylums. The initial proceedings—i.e., the information to be given to a justice of the peace as to the insanity of an individual, his removal to a workhouse or infirmary, and thence to the asylum—devolve upon the relieving officer, and in some cases upon the police-constable. In the 30 unions and parishes into which the County of London is divided the methods of dealing with the insane naturally vary considerably. The great majority of those received into the Council's asylums are described as paupers in receipt of relief, perhaps under the authority of Section 18 of the Lunacy Act, 1890, which enacts that a person who is visited by the medical officer of the union at the expense of the union is, for the purposes of the section, to be deemed in receipt of relief. The number *of patients who are removed direct from their homes to the asylums is very small indeed, the practice* having grown up in the metropolis of removing practically all cases to the workhouse under Section 18. It is to be remembered that a very large percentage of the lunatics who become inmates of the asylums have never had cause to seek poor relief and have only entered the workhouse in consequence of their insanity. Their removal to the workhouse is often considered by the friends a great hardship and the practice is frequently complained of. There is, however, at present, apart from the workhouse, no available house of reception for alleged lunatics. In cases where the relieving officer takes proceedings he does so in a quasi-independent capacity, and as regards the medical examination of the patient the medical officers of the unions have no legal claim to be called in by the justices in preference to any other duly registered and qualified practitioner. In some unions and *parishes of London* the medical officer does not certify lunatics, but an independent outside medical practitioner is called in by the justice of the peace. In the majority of unions and parishes the opposite is the case, and a medical officer of the union certifies and receives a fee for so doing.

The scheme proposed by the committee is that the Council should provide receiving houses to be entirely under its supervision and staffed by its officers, to which an alleged lunatic will be taken instead of to the workhouse. The medical superintendent of the receiving house will have power to detain the alleged lunatic for not exceeding three days, but before the expiration of that period he must bring him before a justice or else discharge him. The medical superintendent is to report to the justice whether, in his opinion, the alleged lunatic should be sent to the county asylum or be detained in the receiving house. If the justice decides that the case is one for asylum treatment, the usual proceedings under the Lunacy Act, 1890, will be taken. If, however, he decides that the case is one for detention in the receiving house, the justice shall call in the superintendent, and may, if he thinks fit, call in any other medical practitioner, and after investigation order the alleged lunatic to be detained in the receiving house. The detention order only remains in force for six weeks; extensions not exceeding three weeks at a time may be made by a justice if thought necessary. During his detention in a receiving house the patient will not be designated a lunatic or a pauper. At any time during the period of detention the medical superintendent, if he thinks the patient should be removed to an asylum, may bring the patient before a justice with a view to the ordinary reception order being made.

The advantage of the proposed scheme, continues the committee, will be apparent. The alleged lunatic, directly he enters the receiving house, will be under the care of medical men who have specialised in mental disease. The most experienced alienists are of opinion that the increase of insanity which has been apparent in London during recent years can only be limited by the proper early treatment of cases. Such treatment would be provided in receiving houses, and thus, without doubt many persons who are sent at present from the workhouses to asylums would not need to go to asylums at all, but would improve and recover at the receiving houses. In connexion with these there could be, if required, an out-patient department which would enable persons who needed it to obtain advice. Thus it is believed that many cases of incipient mental disease might be arrested, and the need for long seclusion in an asylum avoided. The Bill proposes that the certification of lunatics for detention in an asylum should be placed in the hands of the medical officers attached to receiving houses, and in this it coincides with the spirit of the recommendations of the Royal Commission. There would be discrimination as to the necessary treatment and classification of each patient, and thus only persons who required detention in an asylum would be sent there. The Bill proposes also to obtain power for the provision of ambulance stations and ambulances which would enable lunatics to be brought to the receiving house and to be transferred to the asylums with proper care and attention. There would be considerable economy in this, as at present each union makes its own arrangements for the removal of lunatics, and at times the arrangements leave much to be desired.

The committee thinks the special circumstances of London call for immediate action, and, as it seems improbable that the Government will introduce early legislation on the lines of the report of the Royal Commission, it holds that the County Council should itself make a move in the matter. When the question of providing receiving houses was before the Council in 1899 it was suggested that four should be established, each to accommodate 250 patients, the approximate expenditure being £500,000. The committee had subjected this scheme to severe pruning, and now proposed the establishment of two receiving houses, each for 250 patients, one on the north and one on the south of the Thames. By utilising part of the site being purchased for a mental hospital under the terms of Dr. Henry Maudsley's gift, the committee thinks the total cost of the scheme should not exceed £150,000 to £180,000.

The finance committee in a report on the financial aspects of the proposal points out that there would be a saving to the ratepayers because (1) the early treatment of incipient mental cases would minimise the increase of insanity; (2) the certification of patients would be done mainly by the medical officers of receiving houses without extra fee; (3) the conveyance of patients from the receiving houses to the asylums would be more economical than their conveyance from 29 different unions. The cost falling upon the Council would be (1) capital cost of buildings; (2) repair of buildings; (3) possible cost of maintenance of out-patients' department; and (4) pensions of staff. As regards maintenance of patients, this would be recovered from the guardians, but the cost in the receiving houses might be more than in the workhouses or infirmaries.

The finance committee goes on to say that in its opinion the arguments which had been adduced by the asylums committee in support of its proposals are such as to warrant the Council in obtaining Parliamentary powers to establish as an experiment *one* receiving house. It appeared to the finance committee inexpedient and unnecessary to obtain any further powers at present. In the event of one receiving house being established and proving a success, there would be no difficulty in obtaining additional powers. The committee is prepared to support the proposal if its scope is limited in this direction. By proceeding in a tentative and cautious manner the Council would avoid the danger of anticipating Government action upon the report of the Royal Commission. The committee adds, in conclusion, that the possibility of establishing the receiving house on the site of the proposed mental hospital influenced it greatly in coming to its decision, as it seemed to point to the possibility of trying an important experiment on a comparatively small scale.

The report will be considered by the County Council next week.

THE
TWELFTH INTERNATIONAL CONGRESS ON ALCOHOLISM.

The Twelfth International Congress on Alcoholism, of which the Duke of Connaught is the honorary President, was opened on July 19th, when the acting President, Lord Weardale, delivered an inaugural address at Kensington town-hall. This is the first time that the Congress has met in London, and the delegates representing 16 foreign Governments, the self-governing and Crown colonies, and protectorates received a cordial welcome from their colleagues in this country.

The temperance societies in the United Kingdom were well represented, and on behalf of the British Government departments there were present Mr. W. P. Byrne, C.B., Assistant Under-Secretary of State, representing the Home Office; Mr. H. B. Simpson, C.B.; Mr. J. Pedder; Mr. G. A. Aitkin; Dr. H. B. Donkin, Commissioner of Prisons; Dr. R. W. Branthwaite, inspector under the Inebriates Acts; Sir Robert Baxter Llewelyn, K.C.M.G., representing the Colonial Office; Dr. Arthur Newsholme, chief medical officer, and Dr. Arthur Downes, senior medical Poor-law inspector, representing the Local Government Board; and Dr. Janet Campbell and Dr. Alfred Eichholz, representing the Board of Education.

Lord Weardale said that he took the chair in the unavoidable absence of the honorary President, whose keen interest in the cause of temperance was well known and appreciated by all present. The temperance question was a vital one to humanity, and it was one in which a large amount of educative work had yet to be done. The earliest of these congresses was only held in 1885, and this was the first time that the Congress had held its proceedings in London, but national education was bringing to the rising generation a consciousness of the evils of alcoholism that would bear good fruit. To his mind the most important question was the relation of the drink habit to the welfare of the child, while he was glad that something had already been done by means of legislation to protect children from the influence of alcohol. This was a matter which would receive the attention of the Congress, while among other important questions to be discussed when dealing with the prevention of alcoholism was the medical side of the matter. On this important contributions to their deliberations would be made.

Dr. von Strauss und Torney, President of the Senate of the Supreme Administrative Court of Berlin, said that he had been asked by Herr von Bethmann-Hollweg, the Chancellor of the German Empire, to express on his behalf his appreciation of the high aims which animated the Congress. The most important purpose in life was the promotion of the economic welfare of nations, and the principal obstacle to the attainment of that end was the abuse of spirituous liquors. Obviously the same means could not be used by all nations to bring about the desired end, but the proceedings of the Congress should have the effect of making the nations understand better the difficulties under which each had to work in order to do away with the evils consequent upon the abuse of alcohol.

The Rev. N. C. DALHOFF (Copenhagen) said that in Denmark the use of light beers was increasing and the use of beers of heavy alcoholic strength was decreasing. Denmark was living down the reputation of being a brandy-drinking country.

Dr. RAGNAR VOGT (Christiania) remarked that in his country the consumption of alcohol had been brought down to about a fourth of what it used to be during the past half century.

The Hon. G. F. COTTERILL (Washington) said that as long ago as 1812 a temperance organisation was formed in America, and that the United States had never recognised any vested rights in the drink traffic.

Sir JOHN COCKBURN and others having addressed the Congress, it was announced that the Queen of Holland had invited the next Congress to meet at the Hague in 1911.

In the afternoon the exhibition was formally opened by the Dean of Hereford. The exhibition illustrates the machinery of temperance work in various parts of the world. It includes literature, diagrams, lantern slides, photographs, models, chemical apparatus, regalia, postcards, medals, and a variety of objects of interest to the temperance reformer generally.

In the evening Mr. Lewis Harcourt, M.P. (First Commissioner of Works), held on behalf of the Government a reception for delegates in the Imperial Institute. Invitations were issued to more than 2000 guests. Those present included the Crown Prince of Sweden, the Swedish Minister, Lord Weardale, Lord and Lady Carlisle, Lord Saye and Sele, Field-Marshal Sir George White, the Dean of Hereford, the Hon. Mrs. Leigh, Sir John Kennaway, M.P., Sir F. Hodgson, the Hon. J. H. Turner, Sir T. Glen-Coats, M.P., Sir J. Batty Tuke, M.P., Professor G. Sims Woodhead, Lady Horsley, Dr. Clifford, Mr. Leif Jones, M.P., Surgeon-General G. J. H. Evatt, the Bishop of Croydon, Sir Percy Bunting, Canon Hicks, Sir T. P. Whittaker, M.P., Sir H. Hesketh Bell, Surgeon-General Pleadwell, Mr. C. H. Roberts, M.P., Lady Cecilia Roberts, Mr. J. S. Higham, M.P., Mr. W. McAdam Eccles, Sir E. Stafford Howard, the Archdeacon of London, Sir John Cockburn, Major Lugard, Dr. C. F. Harford, Colonel L. G. Fawkes, Colonel G. H. Bolland, and Mr. Mark H. Judge.

The real work of the Congress commenced on the morning of July 20th at the Kensington Town-hall, when papers were read on Juvenile Temperance, by Miss CORA STODDARD (Boston, U.S.A.); on Temperance Education in the School in Various Lands, by Herr J. GONSER (Berlin); and on Temperance Effort in Juvenile Societies throughout the World, by Madam ALLI TRYGG-HELENIUS (Helsingfors).

Miss Stoddart contended that if the child were instructed in temperance principles moral and spiritual ideals would be strengthened, but that such instruction must be begun early. Herr Gonser's paper was an optimistic plea for the continuance of temperance teaching, while the paper of Madam Trygg-Helenius was descriptive of the various juvenile temperance leagues. In the discussion which followed the reading of these papers emphasis was laid upon the importance of the personal factor of the teacher; it was upon this that the value of instruction in temperance principles, dietetic principles, and hygiene depended. As to the relative advantage of relying, in connexion with thorough instruction in temperance principles, upon personal conviction among the teachers, opinion seemed to be divided, many holding that legislative action would be more generally effective than private sentiment.

After the midday adjournment the conference met at the conference room of the Imperial Institute under the presidency of Mr. J. BYSTROM (Stockholm), when papers were read on Temperance Teaching in Higher Schools, by Miss A. W. RICHARDSON (London); on How to reach the Student Class, by Mr. IVAR THULIN (Stockholm); and on How to Educate the Teachers, by Herr J. PETERSEN (Kiel) and M. AUBERT (Paris).

In the afternoon a reception was held at the London Temperance Hospital by the British Medical Temperance Association, when the guests were received by Professor Sims Woodhead and Sir T. Vezey Strong.

Dr. A. HOLITSCHER (Carlsbad) read a report on Alcohol in Lobar Pneumonia and Enteric, founded on statistics from 47 hospitals, in 18 of which the plan of alternating treatment had been adopted. The purpose of this plan was to secure the most reliable proof as to the effect of alcoholic and non-alcoholic treatment. Among 238 cases of pneumonia treated with alcohol the death-rate had been 24·3 per cent.; among 248 cases treated without alcohol it had been 21·3 per cent. Of 47 cases complicated with delirium tremens, alcohol had been prescribed in 21, of which 15 ended fatally, while of the 26 patients treated without alcohol only nine died. While alcohol could not be made responsible for the difference between the 24·3 and 21·3 percentages owing to the smallness of the number of patients reported on, he thought the investigation demonstrated the complete failure of alcohol as a curative agent in such cases. Of the 161 typhoid patients reported on by eight institutions, 80 had been treated with alcohol, of whom 15 died, and 81 without alcohol, of whom 12 died.

Professor SIMS WOODHEAD said that the majority of medical men who had investigated the subject had arrived at the conclusion that it was necessary to revise their opinions as to the value of alcohol as a therapeutic agent. While admitting that sufficient evidence could not at present be obtained to put the case convincingly before the public, it was a fact that medical opinion was tending towards that which was held by those who discarded alcohol.

In the evening the Norman Kerr lecture was delivered by Professor TAAV. LAITINEN (Helsingfors) in the theatre of the Victoria and Albert Museum, the subject being the Influence of Alcohol on Immunity. The lecture was well attended, and was found by the audience to be both instructive and suggestive. It is referred to at some length in a leading article this week.

At the third general meeting, which was held in the Kensington Town-hall on July 21st, Dr. IMRE DOCZI read a paper on Alcohol and its Effects on the Child; Professor HERCOD took for his subject the Legal Protection of Children; and Mrs. BRAMWELL BOOTH spoke on Alcohol in its Relation to the Home. The Scientific Section continued its work and in the evening a public demonstration was held in the Queen's Hall, the LORD CHIEF JUSTICE presiding. The Congress will close on Saturday, July 24th, with a farewell *déjeûner* to the foreign guests.

(To be continued.)

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 23rd, 1831.

USE OF HUMAN FAT

IN THE ARTS, ITS ECONOMICAL APPLICATION TO THE PURPOSES OF FUEL AND FOR FEEDING VARIEGATED LAMPS.

(Extracted from the Annales d'Hygiène Publique, &c.)

AT this period, 1813, a circumstance occurred in Paris, which, by its singularity and the importance attached to it by the government, deserves to be recorded. The servants of one of the anatomical theatres having been informed against for trafficking in human fat, were watched for some days by the spies of the police, and were shortly detected in the fact. The affair appeared sufficiently serious to be laid before the minister of general police. In the report drawn up on the subject, it was viewed in a moral and medico-political light, and the principle was laid down, that this fat, proceeding from bodies deceased in the hospitals, might propagate diseases, and even compromise the lives of those who touched it. It was proved on the investigation of the affair, that there existed amongst the servants of the Faculty of Medicine, and of the private theatres, a kind of association for the purpose of trading in this material; that the fat not previously melted was used to grease the wheels of their waggons—that *several quacks purchased it as a remedy in painful diseases;* but it was especially consumed, and in enormous quantities, by the enamellers and false-gem makers, who bought it under the name of dogs or horse fat. Two thousand pounds of weight were found in the dwelling of one of the servants of the School of Medicine, 20 lbs. with another, 400 kilogrammes with a third, and two barrels full were seized with a fourth. A waggon drawn by two horses, and assisted by three porters, was required to draw this enormous quantity of fat to the Montfaucon sewer, into which it was projected.

In order that no public alarm should be created, or any popular commotion excited, the affair was tried with closed doors, and the culprits sent to the Bicetre for six months. In the different interrogations to which they were subjected, they confessed that they had repeatedly sold the fat at seventeen sous the pound, and that they found it a source of much emolument. It is, indeed, surprising that the government did not obtain earlier information on this matter, for the servants made no mystery about it, and they rendered the fat publicly in the anatomical theatres. On the marriage of Napoleon with Maria Louisa, we saw them prepare with this fat, solidified with some tallow, considerable quantities of flambeaux and lamps, which they sold to the neighbouring spice-men, and which were used for the illumination at the Faculty of Medicine and the Palace of the Luxembourgh.

THE INTERNATIONAL CONGRESS OF NURSES.

A NURSING Congress, convened by the International Council of Nurses, is at present proceeding. The International Council, founded by Mrs. Bedford Fenwick ten years ago, now consists of the National Councils of Nurses of seven affiliated countries—Great Britain and Ireland, America, Germany, Holland, Finland, Denmark, and Canada. This is the second quinquennial meeting of the Council, which has now agreed to hold its meetings every three instead of five years. There have, however, been two interim congresses, one in Paris two years ago and one in Buffalo in 1901. It has been arranged to hold the next meeting in Cologne in 1912, and Fraulein Agnes Karll, President of the German Nurses' Association, has been elected President of the International Council in place of the retiring president, Mrs. Fenwick. As stated in the "Foreword" issued by the honorary secretary, Miss L. L. Dock, "the essential idea for which the Council stands is self-government of nurses, with the aim of raising ever higher the standards of education and professional ethics, public usefulness, and civic spirit of their members."

The scope of the present Congress includes such subjects as Education and Registration, the Nurse in Private Practice, the Nurse as Citizen, the Relations of Nursing and Medicine, the Care of the Insane, the Nurse as Patriot, Morality in Relation to Health, and the Nurse in the Mission Field. Under these headings are classed the various branches of each subject, including School Nursing, Social Service Work, Nursing in Prisons, Massage, Professional Organisation, and Scientific Temperance.

Among those contributing papers to the Conference are Mr. Haldane, the Secretary of State for War; Miss Stewart, matron of St. Bartholomew's Hospital; Fraulein Agnes Karll; M. Mesureur, of the Assistance Publique, Paris; Dr. Anna Hamilton, of the Protestant Hospital, Bordeaux; Mr. D'Arcy Power; Dr. Frederick Rose, assistant medical adviser to the London County Council; Dr. Robert Sevestre, of the Leicester Infirmary; Dr. Robert Jones; and Dr. William Russell, medical inspector of the State Commission in Lunacy, New York.

Besides the affiliated councils, delegates have been sent from France, Italy, Sweden, Belgium, Switzerland, Japan, and Syria, so that the Congress may rightly be deemed an international one, and presents to the public a valuable accumulation of information respecting the progress of nursing and the condition of organisation of nurses in many parts of the world.

The meetings are being held in the Church House and Caxton Hall, where there is also a Nursing Exhibition. The chief features of interest here are the practical exhibits of nurses, organised by the various nurses' leagues and associations. One table is devoted entirely to dressings and appliances used in nursing injuries and diseases of the head, and contains exhibits from ophthalmic, throat, and ear hospitals. There is a well-equipped district nursing section, showing every kind of cheaply constructed emergency appliances, while some amusing models of cottages and rooms depict nursing in the days of Mrs. Gamp and in the hands of the Queen's nurse, the district patient before and after the advent of the nurse, and a typical Irish cabin.

There has been no lack of hospitality to vary the work of the conferences, and besides expeditions, banquets, and other entertainments organised by the honorary officers of the Council, the Congress was invited to receptions at Dorchester House by Mrs. Whitelaw Reid and at the Mansion House. For the visit to Windsor, arranged for Saturday, the King has sent instructions that special facilities be given to the visitors, and the Canadian delegates have received permission from His Majesty to lay a wreath on the tomb of the late Queen Victoria.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8268 births and 3637 deaths were registered during the week ending July 17th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 12·6 to 11·8 per 1000, further declined to 11·5 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 14·0 per 1000, against 14·9 and 13·7 in the corresponding quarters of 1907 and 1908; the mean rate in London during last quarter did not exceed 13·5, against 14·0 and 12·7 in the two preceding corresponding quarters. The lowest recorded annual death-rates last week in the 76 towns were 4·9 in Willesden, 5·6 in Rotherham, and 5·7 in Walthamstow and in King's Norton; the rates in the other towns ranged upwards, however, to 18·2 in Coventry, 19·5 in Warrington, 20·3 in Middlesbrough, and 21·5 in Great Yarmouth. In London the recorded death-rate last week did not exceed 10·6, and was considerably lower than in any previous week of this year. The 3637 deaths from all causes in the 76 towns last week showed a further decrease of 74 from the declining numbers in recent weeks, and included 324 which were referred to the principal epidemic diseases, against 321 and 341 in the two preceding weeks; of these 324 deaths, 114 resulted from measles, 67 from diarrhœa, 56 from whooping-cough, 35 from diphtheria, 30 from scarlet fever, and 22 from "fever" (principally enteric), but not one from small-pox. The 324 deaths from these epidemic diseases last week were equal to an annual rate of 1·0 per 1000, against 1·0 and 1·1 in the two previous weeks. No death from any of these epidemic diseases was registered last week in Birkenhead, Derby, Stockport, St. Helens, or in 11 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 4·5 in Wolverhampton, 4·6 in Coventry, 4·7 in Newport, and 5·9 in West Bromwich. The fatal cases of measles in the 76 towns, which had been 159, 129, and 138 in the three preceding weeks, declined to 114 in the week under notice; the highest annual death-rates last week from this disease were 2·5 in Norwich, 3·0 in Wolverhampton, 3·3 in Newport (Mon.), and 4·4 in West Bromwich. The 67 deaths attributed to diarrhœa showed a further slight increase upon the numbers returned in recent weeks, and caused the highest proportional fatality in Aston Manor, Rhondda, and Bolton. The 56 deaths from whooping-cough showed a further decline from recent weekly numbers, but caused annual death-rates equal to 1·6 in Swansea and 2·0 in Great Yarmouth. The 35 deaths assigned to diphtheria somewhat exceeded the numbers in recent weeks, and included five in Manchester and Salford, and three each in Birmingham, Hull, and Newcastle-on-Tyne. The 30 fatal cases of scarlet fever were fewer by nine than those in the previous week, and included five in Manchester and Salford and three in Blackburn. The 22 deaths referred to "fever" exceeded the low number in the previous week by 13; they included six in Manchester and Salford and three in Blackburn. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had steadily increased in the six preceding weeks from 2228 to 2647, had further risen to 2737 on Saturday last; 415 new cases of this disease were admitted to these hospitals during last week, against 390 and 371 in the two preceding weeks. The registered deaths in London last week referred to pneumonia and other diseases of the respiratory organs, which had been 158 and 154 in the two previous weeks, further declined last week to 106, and were 21 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London last week included but three which were directly referred to influenza, against 13, 11, and seven in the three preceding weeks. The causes of 28, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during last week were again duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Salford, Nottingham, and in 51 smaller towns; the 28 uncertified causes of death in the 76 towns included five in Birmingham, and two each in London, Bootle, Warrington, Tynemouth, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 944 births and 448 deaths were registered during the week ending July 17th. The annual rate of mortality in these towns, which had been equal to 13·3 and 12·9 per 1000 in the two preceding weeks, further declined to 12·5 in the week under notice. During the 13 weeks of last quarter the death-rate in these Scotch towns averaged 16·0 per 1000, while in the 76 large English towns the mean death-rate during the same period did not exceed 14·0. The death-rates last week in these Scotch towns ranged from 10·3 and 11·4 in Leith and Glasgow, to 15·6 in Perth and 18·8 in Dundee. The 448 deaths in the eight towns last week showed a further decline of 14 from the numbers in the two preceding weeks, and included 40 which were referred to the principal epidemic diseases, against 54, 37, and 36 in the three preceding weeks. These 40 deaths were equal to an annual rate of 1·1 per 1000, against 1·0 in each of the two previous weeks; the rate last week from the same epidemic diseases in the 76 large English towns did not exceed 1·0 per 1000. Of the 40 deaths last week from these epidemic diseases in the Scotch towns, 16 resulted from whooping-cough, 11 from diarrhœa, six from diphtheria, three from "fever," and two each from measles and scarlet fever, but not one from small-pox. The 16 fatal cases of whooping-cough showed an increase of four upon the number in the previous week, and included six in Glasgow and three each in Edinburgh, Dundee, and Aberdeen. The 11 deaths attributed to diarrhœa were fewer by one than those in the previous week; four occurred in Glasgow and two both in Edinburgh and in Dundee. The six deaths from diphtheria exceeded the numbers in either of [illegible] week, and included one each in Edinburgh and Paisley. The two deaths from scarlet fever were returned in Glasgow and Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 71 and 61 in the two preceding weeks, further declined to 56 in the week under notice, and were seven below the number in the corresponding week of last year. The deaths in the eight towns last week included 20 which were referred to different forms of violence, including 11 in Glasgow and three in Edinburgh. The causes of 24, or 5·4 per cent., of the deaths in the eight towns last week were uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 19·6, 18·5, and 15·6 per 1000 in the three preceding weeks, rose again to 16·9 in the week ending July 17th. During the 13 weeks of last quarter the death-rate in the city averaged 20·9 per 1000, whereas the mean rate during the same period did not exceed 13·9 in London and 15·8 in Edinburgh. The 129 deaths of Dublin residents from all causes registered last week showed an increase of 10 upon the number returned in the previous week, and included 11 which were referred to the principal epidemic diseases, against 13 and three in the two preceding weeks. These 11 deaths were equal to an annual rate of 1·4 per 1000, the death-rate from the same epidemic diseases last week being equal to 1·0 in London and in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin last week, five resulted from diarrhœa, three from diphtheria, two from measles, and one from "fever," but not one either from scarlet fever, whooping-cough, or small-pox. The fatal cases both of diarrhœa and of diphtheria showed an increase upon recent weekly numbers. The 129 deaths at all ages included 24 of infants under one year of age and 31 of persons aged upwards of 60 years; these numbers scarcely differed from those in the previous week. Three inquest cases and four deaths from violence were registered during the week; and 53, or 41·1 per cent., of the deaths occurred in public institutions. The causes of two, or 1·5 per cent., of the deaths in the city last week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all but two of the 979 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was equal to 4·6 per cent.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel George E. Weston retires on retired pay (dated July 17th, 1909).

Lieutenant-Colonel William B. Day, from the Half-pay List, is restored to the establishment with precedence next below P. C. H. Gordon (dated July 1st, 1909).

The undermentioned Lieutenants to be Captains (dated March 1st, 1909):—James S. Dunne and Arthur D. O'Carroll.

Lieutenant Gilbert G. Collet, from the Seconded List, is restored to the establishment (dated July 17th, 1909).

Captain Travis C Lucas is seconded for service on the Staff of the Governor of Bombay (dated August 1st, 1908).

Lieutenant-Colonel M. W. Russell has been appointed Staff Officer to Principal Medical Officer, Eastern Command, vice Lieutenant-Colonel C R. Tyrrell, who has been appointed Administrative Medical Officer, Bordon District.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of the following officers of the Indian Medical Service:— Lieutenant-Colonel Henry George Luther Wortabet (dated June 22nd, 1909). Lieutenant-Colonel Alexander Silcock (dated March 25th, 1909) Lieutenant-Colonel Arthur Gervase Hendley (dated June 25th, 1909).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List, Lieutenant Denis Murphy to be Captain (dated July 4th, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: The promotion to the rank of Lieutenant-Colonel of Major (Honorary Major in the Army) Charles Stonham, C.M.G., bears date April 1st, 1908.

1st South Midland Mounted Brigade Field Ambulance: Captain William H. Stephen to be Major (dated June 21st, 1909).

2nd Highland Field Ambulance: Lieutenant John Innes to be Captain (dated June 2nd, 1909).

1st London (City of London) Field Ambulance:—The undermentioned officers to be Captians: Lieutenant Percival G. A. Bott (dated April 30th, 1909), and Lieutenant Andrew Elliot (dated June 17th, 1908).

3rd Lowland Field Ambulance: William Kelman Macdonald to be Lieutenant (to be supernumerary) (dated April 1st, 1909).

3rd Wessex Field Ambulance: Lieutenant-Colonel Harry

M. Brownfield resigns his commission, and is granted permission to retain his rank and to wear the prescribed uniform (dated June 5th, 1909). Edmund Alderson to be Lieutenant (dated June 16th, 1909).

For Attachment to Units other than Medical Units.—Samuel Ryder Russell Matthews to be Lieutenant (dated May 1st, 1909). Albert Alexander Gunn to be Lieutenant (dated June 16th, 1909). Thomas Nash Thomas to be Lieutenant (dated June 17th, 1909).

VOLUNTEERS.

1st Cadet Battalion, The Manchester Regiment: Surgeon-Major Israel J. E. Renshaw resigns his commission (dated May 29th, 1909).

TEMPERANCE IN THE ARMY.

The annual report of the Royal Army Temperance Association for 1908-09 is excellent reading. It is the twentieth of its kind, and it contains a record of progress which has absolutely no drawbacks. In 1889 there were only 12,120 members of the association, which the Rev. J. Gelson Gregson had originally founded; now there are 30,614, the increase in the past two years alone having been 4704. Taking the normal strength of the British garrison in India as about 72,000, the proportion of temperance men is very high indeed, and there are signs that these numbers will continue to rise. In fact, there is reason to hope that in a few years' time one-half of the soldiers in British units will have become voluntary total abstainers. As the late secretary, the Rev. J. H. Bateson, happily puts it: "The association has become an army within an army—an army that is always absolutely sober." The effect of abstinence on the health and physique of men serving in a tropical climate need scarcely be dwelt upon; and there is also the higher moral tone which comes when the soldier leads a steady sober life. The support given to the association by the higher military authorities and regimental officers has been naturally of the warmest kind, and among the rank and file the old prejudice against the teetotalers has long since died out. The attractions offered in the matter of membership are such as are best calculated to win intemperate men from their demoralising habit, and to confirm the abstainer in his intention to keep the pledge that he has taken. The young soldier in particular, who is open to many temptations on arrival in India, benefits greatly by the operations of the association, and the State is the gainer by the sobriety which now reigns almost supreme throughout the cantonments of the country. Mr. Bateson has just retired from the secretaryship of the Royal Army Temperance Association after 20 years of unselfish labour, and he leaves to his successor an admirable organisation which cannot fail to endure. He carries with him the gratitude of many thousands of men who have reason to be thankful for all his efforts in the cause of army temperance.

Correspondence.

"Audi alteram partem."

MALTA FEVER ON THE RIVIERA.

To the Editor of THE LANCET.

SIR,—In the interest of those who may visit the Riviera next season it is, I think, desirable that the facts of the following case should be made known.

This year a gentleman, who was previously in good health, stayed for six weeks at one of the most frequented health resorts (?) there. He lived the ordinary life of a visitor, spent a good deal of time on the golf links, and returned to London on Easter Monday. For some days before starting for home he had been feeling unwell in the evenings, but neither then nor immediately after his return was the exact nature of his ailment recognised. As soon as it was found that he had a rise of temperature in the evening it was decided to have his blood tested for the reaction given by the organism of Malta fever. The result was "positive," and has since been frequently confirmed, and he has been in bed and seriously ill for 12 weeks suffering from that disease. This case is, in my experience, unique, but I am far from suggesting that it is the first of the kind. Probably if attention is called to it others will be reported and the true nature of many obscure illnesses which have followed a visit to the Riviera will be recognised. Malta fever is known to have a wide geographical distribution, but that an ordinary visitor to the Riviera runs a risk of acquiring the disease has not, I think, hitherto been appreciated. Possibly, in some quarters it will not be so even now. Sir Alfred Keogh has kindly furnished me with the following.

Return showing the Number of Admissions to Hospital for Malta Fever amongst the Troops Serving in Malta.

Year.	Number admitted.	Remarks.
1904	320	—
1905	643	—
1906	119	From Jan. 1st to June 30th.
1906	42	From July 1st to Dec. 31st.
1907	11	—
1908	4	—
1909	0	From Jan. 1st to June 24th.

The discovery that infection was chiefly conveyed by goats' milk was made in June, 1906. Is it possible that the goat owners of Malta, finding that there is no longer a sufficient demand for the milk of their infected herds, have shipped them off to the towns on the Mediterranean coast?

In the official statistics of Malta it appears that among the "exports of local produce as reported by shipping agents" there were in 1906-07: "sheep and goats," 764; in 1907-08, 778; the proportion of goats is not given. Of the goats examined by the Commission 50 per cent. were found to be affected by the disease, and 10 per cent. were actually excreting the micrococcus in their milk. That the export of infected goats is a source of danger is shown by the case of the s.s. *Joshua Nicholson*. In 1905 this steamer shipped 65 goats at Malta for export to the United States of America. Their milk was drunk by the captain and many of the crew, the result being that an outbreak of Malta fever occurred on board the vessel, almost all who drank the milk being affected. When the goats reached America they were placed in quarantine, but that they were still infective was proved by the fact that a woman who drank their milk acquired the disease.

It would be interesting to know the number and destination of the goats exported from Malta since July, 1906. I commend this inquiry to the government of that island.

I have no personal experience of the taste of goats' milk in tea or coffee, but it is said by some to be unpleasant; if so, it is probably but little used in the hotels on the Riviera.

The occurrence of the organism of Malta fever in cows has been observed in a considerable number of instances. Have the cows on the Riviera become infected?

In the process of making cream cheese nothing, so far as I am aware, is done to ensure that the milk is sterile, and failing that cream cheese made from goats' milk must be regarded as capable of conveying infection; in this case, indeed, it appears to have been its probable source.

It is, I submit, incumbent upon the sanitary authorities of the towns of the Riviera to at once institute an investigation into the bacteriological purity of the supply of the cows' milk, goats' milk, butter, and cream cheese, and until this has been done and the question herein raised has been satisfactorily settled it will be well for visitors to the Continent in search of health either to avoid the Riviera or to be well assured that at the hotels at which they may reside all possible precautions have been taken to protect them from Malta fever.

I am, Sir, yours faithfully,

July 20th, 1909. J. K. FOWLER.

THE NATIONAL LIBRARY OF WALES.

To the Editor of THE LANCET.

SIR,—Speaking from the presidential chair of the National Eisteddfod at the Albert Hall, London, on June 16th last, the Prime Minister, referring to the National Library of Wales, said: "That National Library will, I trust, become the centre, the home, the gathering and the training ground of Celtic scholarship in this country in the years that are before us. It already possesses, either actually or in promise, some of the most valuable manuscripts and books which it is possible to accumulate for those who desire to explore the antiquities of Celtic literature and Celtic history." The Prime Minister went on to point out that it was a patriotic duty to assist the National Library and the National Museum by "adding to the treasures of which these great national institutions are to be the storehouse."

The National Library of Wales was founded by Royal Charter granted by H.M. the King in 1907, and entered upon the first stage of its existence on Jan. 1st of the present year in a temporary building at Aberystwyth, a building admirably adapted for the storing and cataloguing of the collections pending the removal to the permanent building which will be erected on a magnificent site of four acres close to the town of Aberystwyth, generously given for the purpose by the Right Hon. Baron Rendel. A large number of valuable gifts of books, manuscripts, prints, and drawings has already been made to form the nucleus of the library, which at this moment contains the finest collection of Welsh MSS. in existence, including the famous Hengwrt and Peniarth MSS.; the collection of MSS. and early Welsh books made by Moses Williams, afterwards the property of the Earls of Macclesfield; and a number of MSS. derived from other collections. The Hengwrt Library includes not only the oldest texts of Romance literature, but also one of the most valuable MSS. of Chaucer's "Canterbury Tales" and other MSS. of great importance. The number of printed books already in the library is nearly 50,000. We need, however, very many books in Celtic literature and, even more, works of general reference, standard books in English and other languages, sets of transactions of literary, historical, and scientific societies, sets of the great periodicals, dictionaries, encyclopædias, and many other books of various kinds which we have no funds to acquire.

The Charter provides for the circulation of duplicate books for educational and research purposes, and this will be an important feature of the work of the library. The case of Wales is exceptional. Its University consists of three national colleges situated at Aberystwyth, Bangor, and Cardiff, while there are other important centres of educational activity, all urgently in need of the aid which it is hoped the National Library will be able to give to the higher branches of study. I wish particularly to state that while the Celtic side of the library must be its strongest feature, yet the object for which it was founded is much wider. It is to be a national library in the best sense, designed to afford in Wales that opportunity and encouragement for study and research hitherto wanting, and the lack of which has placed Wales at a disadvantage as compared with the other divisions of the United Kingdom and with other countries. England, Scotland, and Ireland enjoy great privileges under the Copyright Act which Wales has not received, and can hardly now expect to receive. Three libraries in England and one each in Scotland and Ireland are entitled to one free copy of every book published in the British Islands, while five or six other libraries which formerly had the same privilege now receive an annual grant from the public funds in lieu of it.

It is contemplated to proceed, as soon as circumstances will permit, with the erection of permanent buildings, and plans have been provisionally adopted. A sum of £21,000 has been subscribed towards the building fund. To erect a suitable and The contributors rts of Wales and Monmouthshire, and many residing in London and elsewhere, including Welshmen abroad. The fund is a truly national one, and is made up of sums ranging from £5000 to 3*d*. The quarrymen of Festiniog and neighbourhood, for instance, made up a list of 744 names for a contribution of £70 18*s*., while the teachers of Cardiganshire agreed to make up £100. In Carmarthen, Swansea, Cardigan, Aberayron, and other centres, large and small, committees were formed to collect subscriptions. The contributors to the fund fully represent the Welsh people and their enthusiasm for the National Library is clearly shown. The library has also received gifts from kindred institutions. The British Museum, the Library of Congress at Washington, the Smithsonian Institution, the Corporation of London, the John Rylands Library, Manchester, the National Library of Ireland, and the principal public libraries have each sent sets of their publications, while the University of Oxford has made a grant of publications of the Clarendon Press. Several eminent scholars at home and abroad have also sent gifts of books, in many cases spontaneously, and with a graciousness which greatly enhances the value of their gifts.

The library is managed by a court of governors and a council, to which bodies members are nominated by H.M. Privy Council, by the county and borough councils of Wales and Monmouthshire, the University of Wales, and the three University Colleges. The maintenance is provided by a grant in aid from H.M. Treasury, which at present only provides for bare working expenses. No sum for purchasing the large number of necessary books is at present available.

I venture to ask those of your readers who feel an interest in this effort to bring within the reach of the residents in Wales the advantages which a National Library offers to make gifts of books or money for the book fund and donations to the building fund.

Communications may be addressed to me at the National Library, Aberystwyth.

I am, Sir, yours faithfully,
JOHN WILLIAMS, President.
Plâs, Llanstephan, Carmarthen, July 12th, 1909.

METHODS OF BARBARISM IN ITALIAN HOSPITALS.

To the Editor of THE LANCET.

SIR,—The two events denounced in your columns under this title by a correspondent in Rome as having taken place in our hospitals—namely, the expulsion of a doctor from one of them on account of "moral turpitude" and of a sister from the other—are unfortunately true, but they took place with an interval of several years between them and have obviously been brought together in order to disparage our hospital institutions. I may add that the guilty persons received prompt and exemplary punishment. The other *irregularities*, of which, according to your correspondent, the two facts mentioned serve as a small demonstration, are not known to us, and we invite him to expound them in detail and to report concrete facts. Thirdly, the neglect of dying people on the part of sisters and nurses has never been shown to exist either in the Policlinico or in the other Roman hospitals. Fourthly, the confidence of the Roman public in the Policlinico and the other hospitals not only is not shaken but is steadily increasing, as is shown by the constantly rising number of patients and the fact that among these are many belonging to the leisured classes. Fifthly, our medical *personnel* is not inferior to that of other hospitals in other countries, and if the actual staff of assistants has not so far attained perfection, still, it has not all the faults attributed to it by your correspondent, while it is undeniable that it is improving steadily owing to carefully considered recruiting and a wider development of nursing schools. So much for the sake of truth. Then, as regards the close of your correspondent's letter, up to the present time we are really quite unaware of having any Anglo-American protectorate over our hospitals. The Roman hospitals live on their own incomes and on direct subsidies from the State, therefore if there is a limit to Anglo-American loyalty and liberality it is no concern of ours. In the hope that you will publish these few remarks of mine in your widely-read paper,

I am, Sir, yours faithfully,
Professor AGOSTINO CARDUCI,
President, &c.
Rome.

⁂ We publish this letter with pleasure, but it seems to have escaped Professor Carduci's attention that our correspondent was quoting the Italian journals, and gives the reference to much of what he reports as appearing in the *Tribuna*.—ED. L.

THE PROPOSED LEGISLATION IN REGARD TO ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—The present situation with regard to this question requires the careful attention of the medical profession, and the remarks which follow have no relation whatever to the practice of anæsthetics as a specialty, but apply to the general practitioner of medicine in all parts of the kingdom. Dr. F. W. Hewitt has undertaken a most important work in bringing forward a measure to ensure protection to the public from the risks of general anæsthetics in the hands of persons who have not received a complete medical training. His proposals have been opposed by a portion of the dental profession partly on the ground that a very large number of medical practitioners are ignorant of the details and methods necessary for producing efficient anæsthesia for operations in the dental chair. In this statement they are perfectly correct, and this state of affairs has been due to the apathy and supineness of the medical student, who during his curriculum despises the idea of learning practical means of earning a livelihood from a secret conviction that he personally will be wafted into a consultant's chair where kneeling princes will pray for his advice. It is, however, absolutely essential that he should learn to give nitrous oxide and ether in the dental department of his hospital, so that he may become an efficient coadjutor of the neighbouring dental surgeon in that general practice which will have to support him and his family during his working life.

At the present moment, when the dental profession are making some claim to be more familiar with the use of nitrous oxide gas than the medical man, unless the latter opens his eyes to the fact that, by reason of his medical knowledge and training, he is the only proper person to induce and conduct general anæsthesia in all circumstances and decides at once to attend a dental hospital or department to obtain a proper facility with the apparatus and in the procedures involved, he will find during the next decade that a serious rivalry in this respect has been established and that he has cast away a valuable means of livelihood which is not only his birthright but a duty which he owes to the public who become his patients.

A medical practitioner is in a false position who, for no other reason than a want of activity in learning how to control the gas or vapour for the purpose in hand, stands by while his patient is subjected to the action of drugs which are potent enough to cause insensibility at the hands of others whose knowledge of medicine and therapeutics is less than his own.

Surely, if he thinks he is the proper person to be sent for to apply means of resuscitation in case of accident during anæsthesia he should be still more the fit person to prevent the accident from arising. It should be his task to choose the most suitable anæsthetic according to the opinion he forms of the patient's state of health, to produce complete anæsthesia, to discriminate during his administration of this anæsthetic between respiratory and circulatory symptoms, and to apply himself the remedial measures as required.

It is to be hoped that the teachers of anæsthetic administration in the hospitals of this kingdom will see to it that their pupils before qualification can properly administer nitrous oxide and ether for dental operations, and that the general practitioners will bestir themselves so that their present inefficiency in this respect may recede into the past.

I am, Sir, yours faithfully,
H. BELLAMY GARDNER,
Formerly Instructor in Anæsthetics at Charing Cross Hospital.
Harley-street, W., July 19th, 1909.

A SYSTEM OF DIET AND DIETETICS.

To the Editor of THE LANCET.

SIR,—Surely Dr. Young labours his points in endeavouring to support his statement that my views on the Salisbury diet are "incomplete and erroneous." As I pointed out in my previous letter, Salisbury sometimes prescribed 8 ounces a meal at the beginning of treatment; a statement made in my critic's first letter which contradicts his assertion that the "vital" error in my article has reference to quantity. Dr. Young, also, for the sake of his thesis, divided the food into three meals a day, although he complains that I did not refer to the number of meals, and regards that as a "fairly weighty error of omission." Now he assumes I have forgotten that Salisbury repeatedly emphasised that "five hours must elapse between meals." There is nothing in the original article which justifies either of these assumptions, and reference to it will show that the five hours' interval is mentioned in the statement that the water should be given at 6 and 11 A.M. and 4 and 9 P.M., and one or two hours before meals. Surely the reader can understand from those words that either three or four meals can be given and that even under a four meal *régime* the last one need not be later than 10 P.M. Talking of midnight, as Dr. Young does, as the time when the fourth meal would be partaken of, is an exaggeration. The diet received adequate notice, and the idea in Dr. Young's mind that the quantity and number of the meals are the "prominent essentials" obscures the wood by the trees. The essential feature of the diet is that it is one of meat and hot water only. Further I may point out that the strain on the kidneys and organs concerned in the metabolism of protein was not ignored. Surely Dr. Young will not maintain that if only one or two ounces are given for a meal a five hours interval is essential. Many cases do quite well on four-hourly feeds. These are what I call the minutiæ of treatment, the modifications required by the individual patient. I have no reluctance in admitting that 11 ounces, or even 8 ounces, is an unduly large quantity for some cases at the beginning of treatment, but even Dr. Young cannot get away from the fact that Salisbury sometimes prescribed 8 ounces and that in the course of treatment patients sometimes take more.

I am, Sir, yours faithfully,
EDMUND CAUTLEY.
Upper Brook-street, W., July 19th, 1909.

MEDICAL TOPICS AND THE PUBLIC PRESS.

To the Editor of THE LANCET.

SIR,—I am sorry to trespass again upon your space. The Editor of the *Practitioner* is of opinion that in my brief letter to you last week I have not cleared him from a suspicion of having sanctioned the republication of parts of my article in his July number. I am certainly pleased to do so, and to be assured that he had no responsibility in the matter. His permission was not sought.

I am, Sir, yours faithfully,
July 19th, 1909. DYCE DUCKWORTH.

DISUSED INSTRUMENTS AND MEDICAL CURIOS.

To the Editor of THE LANCET.

SIR,—The Medical Missions Committee of the Society for the Propagation of the Gospel are very grateful to an anonymous donor for a case of surgical instruments. They are always very thankful for such gifts for use in mission hospitals and dispensaries abroad or for the equipment of recently qualified doctors about to proceed to mission stations.

They would also, for exhibition purposes, be very grateful for gifts of *native* medicines, charms, or other articles used in the treatment of disease, the stock-in-trade of a Chinese doctor or chemist, or the dress, &c., of an African witch doctor. The object of showing these or similar articles at exhibitions is to contrast the apathetic indifference to human suffering, the heartless and stupid neglect of the sick, or the horrible cruelty to which they are subjected in lands where non-Christian beliefs hold sway, with the work of the medical (Christian) missionary, to whom all life is sacred, and who without distinction of class or creed ministers with loving skill to all alike. Gifts of such articles, accompanied by a brief description of their character and purpose, should be sent, with the name and address of the donor, to the Medical Missions Department, S.P.G. House, 15 Tufton-street, Westminster, London, S.W.

I am, Sir, yours faithfully,
E. H. MOSSE,
Chairman of the Medical Missions Committee, S.P.G.
July 20th, 1909.

THE ROUTINE USE, BY THE OPEN METHOD, OF A MIXTURE OF CHLOROFORM AND ETHER.

To the Editor of THE LANCET.

SIR,—I have read with interest the paper by Dr. Hewitt and Dr. Blumfeld, and also the correspondence following. After the publication of Dr. Hewitt's lectures on General Surgical Anæsthesia in your columns in July, 1907, I tried the C_2E_3 mixture on the open mask and my results corresponded to those described. But I returned to what we call at the Bristol Royal Infirmary the "two-bottle method," the two anæsthetics (chloroform and ether) being in separate bottles and added to the mask as required, as I think it is an improvement on the use of one definite mixture.

By this method the amount of either anæsthetic can be altered at will, an enormous advantage in combating shock. For example, take a case where this "two-bottle" method is used. The anæsthetist sees that the next step of the operation is calculated to produce shock. He is able by adding more ether to his mask to anticipate the surgeon, stimulate his patient, raise his blood pressure, and place him in a position to better resist the effects of the coming manipulation. In this way more ether than required is never used; the type of anæsthesia is excellent; respiration, pulse, and colour remain good; and the amount of anæsthetic used very small, in my experience less than with the mixture.

I should have been glad if Dr. Hewitt and Dr. Blumfeld had given more particulars with regard to the use they make of oxygen, the only reference being in connexion with a case suffering from pneumonia. My own experience leads me to think that, when a patient is very ill and feeble at the time of operation, oxygen used in conjunction with the above method is a very valuable factor in the prevention of shock.

I am, Sir, yours faithfully,
Clifton, Bristol, July 19th, 1909. STUART V. STOCK.

THE ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND AND A MEMBERSHIP QUALIFICATION.

To the Editor of THE LANCET.

SIR,—The holders of the Licentiateship of the Edinburgh Royal College of Surgeons, either alone or conjoined with the Glasgow or other Scottish qualifications, have for a long time laboured under a disadvantage in practice through not having a Membership open to them. The matter has for some years engaged the attention of the Association of Medical Diplomates of Scotland, on whose behalf I venture to ask the publication of the following communication addressed to the Edinburgh College.

I am, Sir, yours faithfully,
DAVID WALSH,
Welbeck street, W., July 21st, 1909. President, A.M.D S.

TO THE PRESIDENT AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.

To the Editor of THE LANCET.

SIR,—May we bring before your readers the claims of the Factory Girls' Country Holiday Fund?

The Fund last year sent away over 5000 of the poorest women and girls of London, some of whom, even some of the youngest, work from nine to 11 hours a day, and are in many cases the chief bread-winners in their families. Many of these girls have been saving up for months for their holiday; the total contribution from them reached, last year, the sum of £1558. But it is obvious that, from wages sometimes as low as 2*s*. 6*d*. a week, the whole cost cannot possibly be paid by them. A fortnight at the country or seaside, including fare, costs on an average 25*s*., yet many factory girls cannot afford even a week, and if they could they would not know where to go. Many have never been out of London at all to stay.

To all, then, who value their annual holiday, we appeal, confident that they will not allow those who are working amid many hardships, to go on working without any change or refreshment. It has been already necessary to refuse all further applications since the end of June, and it is doubtful whether many applicants, numbering some thousands, may not after all be disappointed of their longed-for holiday unless further help be at once forthcoming.

Subscriptions and donations will be thankfully received by the chairman, the Rev. Edward Canney, St. Peter's Rectory, Saffron-hill, London, E.C., and by the honorary treasurer, Herbert Rendel, Esq., 51, Gordon-square, London, W.C.

Yours obediently,
MARY ST. HELIER, NORFOLK,
BEATRICE B. TEMPLE, HENRY SCOTT HOLLAND,
LOUISE CREIGHTON, H. ADLER (Chief Rabbi),
H. L. STEPNEY, ROBERT F. HORTON,
EDW. SOUTHWARK, FRANK LLOYD.
July 21st, 1909.

SANITATION AT SEA.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

FROM EGYPT TO MARSEILLES BY THE MESSAGERIES MARITIMES.—THE BEAUTIES AND ADVANTAGES OF THE ROUTE.—OLD SHIPS WITH GOOD COMPANY AND GOOD CUISINE.—BETTER QUARTERS FOR THE CREWS.—SANITARY PROGRESS IN TONQUIN.—THE MESSAGERIES MARITIMES' MODEL LAUNDRY AT MARSEILLES.

HAVING travelled to Egypt by the Austrian-Lloyd I returned by the French Messageries Maritimes. The two companies work together and give circular tickets, so that passengers may go by the one route and return by the other. For persons who are wintering in Egypt and can afford to stop on the road I would recommend Trieste for the outward journey and Marseilles for the return. Near Marseilles there are numerous half season places where the traveller may gradually prepare for the change of climate. An economic and pleasant way home for those who like the sea would be by the General Steam Navigation Company's ships which sail twice a week from Bordeaux to Tower Bridge, London. From Marseilles to Bordeaux, Arles, Nimes, Aigues-Mortes, Montpellier, Narbonne, Carcassonne, and Toulouse can be visited. They are all on the road and but a few hours' journey from each other. Though not winter stations, still, being in the South of France, they are much warmer than Paris or London. Then by taking a route that is not so direct all the health stations of the Pyrenees can be reached; together with Pau and Biarritz. In regard to the ships from Alexandria to Marseilles, it must be confessed that these are not up to date. They are old boats, and as the agreement between the company and the French Government has now run its course and must be renewed, the building of better ships was deferred until the new arrangement should be concluded. This was all the more necessary, as there was not only the question of the contract between the Government and the company, but a new law pending on the construction of ships and the conditions of navigation. This law has now been enacted and its stipulations are such that it will place the French passenger lines in the very fore rank of progress so [illegible]

ru [illegible] courteous assistance of the company; to embark at Port Said on the *Tourane*, a ship of 6000 tons which was on her homeward journey from Japan, China, and India. To my mind the principal advantages of this line are the sociability, the cheerfulness, the ready wit, and the *savoir vivre* which so specially distinguish the French people. In Cairo I heard some English visitors complain that the discipline on the French ships was not severe enough, and that second-class passengers gained too easily and too frequently access to parts of the ship reserved for first-class passengers. But on pushing the inquiry further I found that the second-class passengers who had rendered themselves obnoxious by their loud and vulgar behaviour were Englishmen, and I can quite understand that the French officers would overlook conduct on the part of foreigners which they would never tolerate on the part of fellow-countrymen. The second great advantage of a French ship is the cuisine, while it is not necessary to pay 2*s.* or 3*s.* for a bottle of ordinary wine which only cost 2*d.* or 3*d.* For the sake of promoting temperance by encouraging the consumption of cheap natural wines instead of spirits all taxes have been abolished on ordinary wine. In France, therefore, the retail price varies from 2*d.* to 4*d.* the litre. In France or on French ships there is consequently no more reason to make a special charge for wine at meals than there is for bread, or pepper and salt.

So far as sanitation is concerned, the *Tourane* has none of the appliances found on modern ships. There is no mechanical ventilation, so that when the weather is bad the conditions below deck, especially among the third-class passengers, must be anything but pleasant. On the other hand, there is no general steerage, but cabins holding six berths with mattresses—in fact, complete beds. The sailors' quarters looked clean and airy, particularly as it was fine enough weather to keep the port-holes open. But heat came from the kitchens, which were too near, and the cooks complained of insufficient ventilation. Some of the firemen had cabins like the third-class passengers, and this is better than what I have seen on English ships. Indeed, in regard to space, bedding, and lockers, the poorest quarters seemed better than what obtains on inferior lines of passenger ships in England. Even the best British ships are only superior because they have mechanical ventilation, and not because there is more space or greater cleanliness. The Chinese and Arabs cook for themselves. The former eat no bread and only half cook their vegetables, but the French *chef* entertained a high opinion of the skill of his Chinese colleague. The crew's closets, and especially those used by the Arabs, were very clean and free from bad odour. The closets consisted of iron troughs with salt water flowing in them all the time. There was no hospital on board, but a first-class cabin with four berths was kept empty to be used as an emergency hospital, though it was not properly situated or furnished for such a purpose. There was a disinfecting stove on deck. It is used once on every journey even when there is nothing to disinfect, but simply to see that it is in good working order. But for this it might happen that when urgently wanted a screw, an indiarubber flange, or other small thing would be missing. The stove is also usually brought into operation on arriving at Suez from the East. The passengers are then asked for all their dirty body linen as a routine, so as to accustom them to the idea and to demonstrate that their linen is not injured by the process. Then when a real danger is present there is not the same resistance nor as many objections offered as there used to be when it was proposed to apply an altogether unprecedented and unknown proceeding.

During the passage I was able to obtain some interesting information from medical officers who had terminated their term of service in Tonquin. The natives, they said, were peaceful agriculturists who only desired not to be molested and to pay as few taxes as possible. They were still oppressed by the mandarins, but they knew that, at least in extreme cases, they could obtain redress by complaining to the French authorities. Consequently, there was a party among the natives that favoured the French occupation. All attempts at scientific farming, I was told, had been dismal failures. The only paying thing a European could do was to buy land and let the natives cultivate it, reserving a share of the profits; this would bring in from 10 to 20 per cent. The French have introduced the usual evils of civilisation, and the resources of the country are strained to pay pensions to those who, having served their time, will spend their money at home. On the other hand, the French have abolished plague and cholera. The natives aiding, the first cases are promptly reported, the patients and contacts are isolated, and then if there are 20 to 30 cases remaining to be dealt with they can soon be stamped out. As sanitary reformers the French have evidently done very good work in Tonquin; but I gathered that it was considered doubtful whether this colonial enterprise is, on the whole, of benefit to the natives. Further, it should be noted, and I was much impressed by the fact, that the latter observation inferred the belief that such enterprise was only justified if it did improve the condition of the natives.

The journey from Egypt to Marseilles affords opportunities of enjoying some magnificent scenery. On approaching the Straits of Messina a commanding view of Mount Etna can be obtained. Then the Straits are so narrow that Reggio and the Calabrian ranges on one side, and the thickly populated verdant mountains of Sicily on the other side, are both quite near enough for the full appreciation of their beauty. On the other hand, it needed good glasses to see the ruins caused by the recent earthquakes. A few hours later, after passing through the Straits, the ship approaches the cone-shaped volcanic mountain island of Stromboli. On the other side of the ship, also well in sight, was the rock-formed Lipari and other wild-looking, picturesque islands, celebrated for the delicious wines obtained from the grapes grown on their volcanic soil. Then on the morrow the ship sails through the Straits of Bonafacio, and here again beautiful views of the coasts of Corsica and Sardinia can be enjoyed; while, finally, the islands of Hyères, the coasts of the French Riviera, and Marseilles itself form a magnificent framework of purple mountains and white glistening towns that wall in the deep waters of the blue Mediterranean.

A very important part of the problem affecting sanitation at sea is the laundry question. An abundant supply of absolutely pure linen is an essential to health and comfort, and this the Messageries Maritimes have taken into consideration from the very beginning. So long as 47 or 48 years ago they purchased a country house surrounded by extensive grounds some three miles outside of Marseilles. It was not a question of being near the ships so as to quickly transport the linen, but of getting away from the dirty atmosphere of the town and of securing plenty of pure air and sunshine to dry the linen. Now, however, Marseilles has so grown that the estate is not so free from the soot and smoke of factories as it used to be. Nevertheless, I have not seen elsewhere and in connexion with shipping companies such extensive open-air drying grounds as those of the Messageries Maritimes laundry near the Pont du Jaret in the rue Saint Pierre. Here all the woollen blankets are dried in the open air, and this not only makes them delightfully fresh and sweet but prevents their becoming like felt, which is a very general consequence of being dried artificially. There is room for several miles of rope to be extended backwards and forwards across the grounds, and here all sorts of linen as well as the blankets can be exposed to the wind, the country air, and the sunlight. It is hardly necessary to insist on the great advantage of this simple natural method of drying. The only disadvantage is that the laundry is a long way from the docks, but a tram line passes close by and a branch line into the laundry will soon be built. Then special cars for carrying linen will be constructed, and these will run straight from the ships to the laundry and back from the laundry to the ships.

When this laundry was first installed there was no machinery and everything was done by hand, but in those days the company had only a few very small ships. In 1852 there were not more than 17 ships, with a total tonnage of 13,600; now there are 68 ships, with a total gross tonnage of 294,973. When one of the larger ships arrives from the Far East it brings some 25,000 pieces of dirty linen. At the laundry something like 3,000,000 different articles are washed during the course of the year. There are a series of large rooms to receive this linen. On one side there is the yard where the carts drive up to the doors of these rooms, and the chief steward accompanies the linen, for which he is responsible till it has been counted out. An opening in the wall of the counting-room serves to receive the linen and convey it to the laundry and a receipt is given to the chief steward; the laundry then becomes responsible. For this it is important to have separate receiving- and counting-rooms, so that no two ships' linen shall be unloaded in the one room. My ship, the *Tourane*, brought no less than 30,000 pieces to wash, and it required a good sized room to sort and count all this. [illegible] once in the hands of the laundry [illegible] to be divided into three classes—the very dirty, the dirty, and the comparatively clean. Each category is washed differently so as to avoid wearing out the cleaner pieces. There are great vats or tubs some five to six feet deep and nearly as wide, and these will hold about 700 kilos weight of linen. With the linen there is some 900 litres of washing water, and this is made to circulate slowly round and through the linen for some six hours. After that the linen can be cleaned much more easily and therefore with less wear. Otherwise the linen could at once be put into the revolving and beating drum or mechanical washers, but it would be necessary to knock the linen about for a much longer time before it would be cleaned.

Wine stains on the table linen are very frequent, and for this the *eau de Javel* so popular with the French laundress is used. It consists of a solution of chloride of lime of stable strength and easy application. After remaining half an hour in the washer where the linen is beaten amid soapsuds the hot soapy water is drained off and replaced by fresh cold water, so delivered as to allow the linen to cool gradually and thus avoid fixing the stains. Ten minutes of fresh-water rinsing follows on this gradual change. To dry the linen it is first placed in a centrifugal hydro extractor, which whirls round so rapidly as to throw the water out, and the linen is then damp but no longer wringing wet. Certain sorts of linen may then be ironed, and there are huge revolving cylindrical rollers no less than 3·50 metres long. Under these two sheets can be passed and ironed side by side. Like those employed at Liverpool in the laundry works of the Cunard Steamship Company, they are much larger than the standard size. I found that at Marseilles they had not introduced any automatic finger-guards. There was nothing to prevent the fingers of the attendants being carried under the roller and crushed. At the Cunard laundry works, as I have described,[1] there is a sort of rod in front of the ironer, and if the fingers press too far forward they will lift this rod before they reach the roller. The raising of the rod at once stops the machine and no accident can happen.

The place where the greater part of the washing is done is like a large and lofty hall with lantern openings on both sides of the roof and windows facing each other along the longitudinal walls. There is therefore plenty of air space and light. The mending rooms are also large and light, but the room for ironing by hand is not important. Machinery has almost entirely taken the place of this sort of work. There is only a little hand ironing to be done and this principally for hotels, for which establishment the company is now beginning to cater, and it will be an advantage for travellers who have to stop at Marseilles to have a sanitary laundry at their disposal.

One of the greatest difficulties in washing ships' linen is to remove rust stains. These are naturally more plentiful at sea than on land. The problem has now been solved, perhaps in a somewhat empirical manner. The rust-stained linen is soaked in a bath placed in the open air and containing a very weak solution of oxalic acid. The secret of success is to never change the water; it may be replenished, but the bath is never emptied, and it is only after it has been in use for about two months that the maximum of effectiveness is attained. Another peculiarity demonstrated by experience is that the result also depends considerably upon the weather. The rust stains disappear much more quickly when the sun shines. The mistral wind, which is not only very violent and cold but ensures the maximum of sunshine and a very dry atmosphere, is also favourable. On the other hand, dull, heavy, cloudy weather is absolutely unfavourable for the process. The rust-stained linen may then have to remain in the solution of oxalic acid all the night. This is likewise the case when the stains are very bad. Generally speaking, it suffices to lay out the linen flat in the tank and let it soak for about four hours. By that time the rust stains will have disappeared. Then the linen must soak in a soda bath for two hours so as to remove the oxalic acid and check its burning action. It will then be found that the linen has not lost any of its strength. Put to the test of a dynamometer it will not break sooner by pulling than if it had not been washed in this manner.

Apart from these ingenious devices it was a pleasure to observe the freshness, ample space, and abundance of light that prevailed throughout the premises. There was an abundance of trees, while flowers, some wild and some cultivated, disputed with the linen for a share of sunlight. The steam, the sloppy wet floor, the hot muggy atmosphere, the sour effluvia of the old-fashioned and small laundries—the characteristics that render laundry work unhealthy—are quite unknown here. The women workers are rarely ill and have no complaint to make on the score of unhealthy conditions.

CHOLERA AND PLAGUE IN RUSSIA AND THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Fresh Outbreak of Cholera in St. Petersburg.

As stated in my last letter (THE LANCET, June 26th, p. 1864) the epidemic of cholera in St. Petersburg, which began in August last, appeared to have come to an end on May 14th (27th). The respite was, however, a very short one. On May 25th (June 7th) the city was once again declared "infected." In the week ending May 30th (June 12th) there were 58 cases of the disease there with 19 deaths. Since then the returns have been as follows:—

Between May 31st and June 6th	...	202 cases,	46 deaths.
,, June 7th ,, 13th	...	548 ,,	155 ,,
,, ,, 14th ,, 20th	...	664 ,,	234 ,,

(All the dates mentioned are according to the Old Style.)

The epidemic so far has been confined to St. Petersburg itself, with the exception of a few cases imported elsewhere by persons coming from the capital. Thus in the week ending June 13th the figures include three such cases, imported respectively to Mariengam (government of St. Petersburg), and to places in the governments of Olonetz and Riazan; and in the last week of the table they include two similar cases, imported respectively to the government of Novgorod and to the town of Riga. All these imported cases have, it is said, been isolated. But the situation is unquestionably a disquieting one. Already the epidemic in the capital may be regarded as of serious proportions (though it is still far from the maximum height of last year's outbreak), and a further extension of the infection to other parts of Russia is almost inevitable. It will be fortunate, indeed, if other countries escape the disease.

In former letters I have referred more than once to the question of the St. Petersburg water-supply. It will be recalled that a Government Commission was recently appointed to study the whole question of the water-supply and drainage of the city. According to the daily papers the expense is estimated at 100,000,000 roubles (about £10,000,000), and this sum it is proposed to raise by a public loan. The works will, it is thought, take about 15 years to complete. It is obvious, therefore, that this great scheme can have no immediate effect on the present epidemic, which will have to be fought with the same inadequate weapons as in the past. But it is very satisfactory that the Russian authorities are taking a large view of their responsibilities, and are contemplating works intended to attack the evil at its root. The problem set before the Commission is, as already pointed out, a difficult one, in view of the topographical conditions at the months of the Neva, and the method by which the problem is attacked and the solution arrived at will be watched with interest by all who are called on to deal elsewhere with such large public health questions.

Plague in Adalia.

[illegible]

in [illegible]

Th[illegible]

in a mill. She had already been ill for seven days, with all the clinical symptoms of an attack of plague, the bubo being in the left groin. The case is recovering. It will be recalled that similar isolated cases of plague occurred in this town in 1905, 1906, and 1908. In last year's outbreak two cases were seen (in a flour mill) on July 26th; then on August 22nd there was a third case, followed on Sept. 5th and Sept. 23rd by two others, making five cases (with three deaths) in all. This year's case has occurred in the same quarter of the town as those of last year. The only measure put in force against Adalia has been a medical visit on departures.

---

[1] See THE LANCET, Sept. 26th, 1908, p. 973

Plague near Beirût.

On July 1st a case of suspected plague was reported from a village in the Lebanon, called Harret Arik, situated about an hour away from Beirût. The patient was a boy, aged 13 years, employed in a tailor's shop in that town. On June 27th he returned to the above-named village in the evening; apparently he was already ill, and shortly presented all the symptoms of an attack of bubonic plague; in this instance also the bubo was in the left groin. A bacteriological examination was made and bacilli were found resembling those of plague. This case also appears to be recovering. As in the case of Adalia, a medical visit has been imposed upon departures from Beirût. It will be recalled that last year three sporadic cases of plague were seen in Beirût between Sept. 19th and 23rd, and that in December there were five cases of the disease in its pneumonic form at the French hospital in that city. It would seem that both here and at Adalia the infection of plague lingers on from year to year without giving rise to anything more formidable than a few sporadic cases of the disease in the human subject. As to its behaviour in rats during the intervals there is, unfortunately, no information.

Plague in Bahrein.

Since the date of my last letter the following returns have been received from Bahrein (in the Persian Gulf):—In the week ending June 3rd, four deaths; in that ending June 10th, two deaths; and in the week ending June 17th, no deaths. Finally, under the clauses of the Paris Convention Bahrein was declared free from plague on July 2nd.

Suspected Cholera on an Indian Ship.

The following remarkable series of incidents recently occurred on a British ship called the *Alavi*. This is apparently the same steamer on board of which three cholera cases occurred at the lazaret of Camaran at the end of last November. (Those cases were mentioned in a letter of mine which appeared in THE LANCET of Jan. 16th last, p. 196). Of the history of the ship between that time and the middle of May nothing is known here. On May 19th she left Calcutta with a cargo of rice and with four passengers. Between Calcutta and Aden, again, three deaths from suspected cholera occurred in members of the crew. These deaths took place respectively on May 21st, May 31st, and June 14th. The symptoms are said to have been those of cholera, and the illness lasted in each instance only one day. The ship called at Berbera and at Aden, where she arrived on June 17th. There she was regarded as "suspected"; the drinking water on board was treated with permanganate of potash and changed; the bilges were also disinfected with carbolic acid, and the crew's quarters, their clothes and effects, were all disinfected. The three patients were all stokers. The ship went on to Jeddah, where she arrived on June 22nd. There was nothing suspicious on board at the time of arrival; nevertheless, the same measures that had been applied at Aden were repeated here, and the passengers were subjected to five days' quarantine. On June 29th, that is seven days after her arrival, another member of the crew (also a stoker) fell ill with symptoms described as those of cholera, but of the "dry" form. The ship left *en contumace* for India, on July 1st, taking the patient with her. Later written reports may perhaps throw further light on this case. It is not easy to see how the diagnosis of cholera of the "dry" variety could be arrived at, in the absence of an epidemic, unless death supervened in a few hours (the so-called "fulminant" form of cholera), which apparently was not the case in the present instance, or unless there was bacteriological evidence of the nature of the illness. Apart from this, however, the occurrence of three deaths on the voyage, at the intervals named, from a rapidly fatal form of disease, resembling cholera, is noteworthy. It can scarcely be more than a coincidence that they occurred on a steamer from which, some six months previously, three cases of undoubted cholera had been isolated at the lazaret of Camaran.

Constantinople, July 12th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

"Afflicted Children."

ON July 10th, under the auspices of the National Special School Union, a meeting was held at which Mr. C. H. Wyatt, director of elementary education, Manchester, gave an address on the need of special schools for afflicted children. Dr. A. Brown Ritchie, chief medical officer to the Manchester education committee, who presided, said that they ought, in regard to the schools for the mentally defective, to aim at getting a higher type of the mentally defective. The lower types of the mentally defective and imbeciles were of no use in the special schools. He said there was a regrettable tendency to keep these mentally defective or very backward children year after year in the elementary schools, instead of having them sent to the special schools. Every year thus spent was the loss of a year. He advocated the teaching in these special schools of manual work. There is no doubt that many of these children, backward and unable to assimilate ordinary teaching though they may be, sometimes show remarkable aptitude in technical pursuits and the use of tools. Mr. Wyatt said that while the public conscience had felt that the blind and the deaf must be taught and trained, he regretted that the care for the mentally deficient, the crippled, and the epileptic, had not secured nearly the same hold on the public mind; hence, little had been done for them. The reason for this was want of knowledge and want of money. The latter was a real hindrance even where the authorities were anxious to do something, and he seemed to think voluntary help was needed before Parliament would be induced to move in the matter. Most members of our profession will agree with his concluding remarks: "Some of them were sure that it would be true economy to provide permanent care for all such helpless persons, seeing that nothing short of this would stop the ever-increasing number of those who, without such provision, came into the world born to a life of misery, it might be of vice, and the unfortunate producers of a miserable progeny—a real danger to national life which must be removed if they were to deal effectively with crime and pauperism."

Post-mortem Examinations.

Some of the Chorlton guardians are in an excitable mood with regard to post-mortem examinations. At a meeting held on July 9th one of them moved a resolution, proposing that the medical officers should state the name and address of any relative who assented to a post-mortem examination being made, also the ground on which the examination was considered desirable, and the conclusions drawn from the examination. These facts were to be entered in a book, which was to lie on the table at each meeting of the house committee. A lady guardian, oddly enough connected with the medical profession, seconded the resolution, and several members spoke in favour of it. Dr. J. S. Orchard, the medical officer, who has held his very responsible position for many years, had written a letter showing how two recent post-mortem examinations had furnished important information that would not have been obtained in any other way; but, in spite of this evidence, the resolution might have passed had not the mover attacked the chairman in terms which led to the breaking-up of the meeting without the resolution being put. The object of the resolution was, apparently, to throw all possible difficulties in the way of obtaining medical knowledge. Whether the question will come up again remains to be seen. It was the sequel to rather an excited meeting held in June, when there was a long discussion on the question of post-mortem examinations, arising from some remarks made by the coroner, which seem to have been hasty.

River Pollution.

With the idea that a river is intended by nature as a convenient receptacle for all the filth that can be turned into it that is held by a large percentage of the population, it is not to be wondered at that such a river as the Irwell, flowing through a populous industrial district, should give endless trouble to the authorities in spite of laws and regulations. It seems, too, a little hard that Salford should get so much of the blame for faults and failings in some measure due to the heritage it receives from the higher reaches of the river. In the days before cotton reigned supreme the Irwell must have been one of the most beautiful of our northern streams, but now, in spite of the efforts made for its purification, its colour is generally black, though sometimes it is green or yellow, according to the pollution used. Its odour is its own. It is therefore not surprising that at the last meeting of the Mersey and Irwell joint committee Mr. Scudder, the chemical adviser, submitted a report which was not altogether satisfactory. Some part of it refers to sewage effluents higher up the river and part to Salford itself. Out of 91 samples from the works of local authorities, 13 were good, 31 fair, 21 unsatisfactory, and 26 bad. At the Salford works there is an increased volume of sewage, but at the present time some of the filters are out of use and only about one-half of the dry weather sewage was being filtered. The subcommittee considered that, even with the whole of the filters in use, the filtration area was inadequate to deal with the flow of sewage. As a result of this the corporation has been asked to give an undertaking to make its filtration area adequate to deal efficiently with the whole of its sewage. To this the town clerk of Salford has replied that the question "is receiving careful consideration." An important complaint was made from the Ashton Cotton Spinners' (Employers) Association respecting the river Tame, which might perhaps give points as to pollution, even to the Irwell. It states that, owing to the very serious pollution, mill-owners who draw their feed water from the river find their pipes and valves corroded to such a degree as to cause great inconvenience, and they feared that unless the corrosion were lessened it "might lead to an accident which would create havoc to life and property in the district." The matter was referred to a subcommittee for special consideration. It is to be regretted that our rivers should become vile and disgusting nuisances.

July 20th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Health Congress.

DURING the last week a Health Congress has been in progress at Leeds organised by the city and University with the help of the Royal Sanitary Institute and the Royal Institute of Public Health, and the presence of nearly 1200 delegates has ensured the success of the gathering. On the evening of July 17th the Lord Mayor of Leeds, Alderman F. J. Kitson, and the Lady Mayoress, received the delegates at the University, and Colonel T. W. Harding, President of the Congress, delivered his presidential address, in the course of which, whilst acknowledging the advantages of modern sanitary science, he doubted whether we were healthier than our fathers, seeing that we had lost much of their simple, rational, and natural way of life. He pointed out that formerly three-quarters of the population dwelt in the country and one-quarter in the towns, but that now this ratio was more than reversed. He referred to the reduction in the mortality from phthisis, but deplored the number of deaths that it still causes. In discussing the declining birth-rate he found some comfort in the reduction of the number of early improvident marriages. He finished his address by a warm approval of physical exercises and training in schools and looked forward to the day of universal military service as one that would bring great benefit to the public health.

The work of the Congress was opened on July 19th. The Lord Mayor of Leeds presided over the session of municipal representatives and described some of the improvements that his corporation has effected in the slum areas of the city. Mr. Percy Robinson read a paper on Town-planning, in which he suggested the formation of advisory expert committees to assist municipalities in that branch of their work. Alderman H. W. Newton read a paper on Labour Colonies, and Councillor F. Anderson one on the Children Act. Sir James Crichton-Browne, vice-President of the Congress, presided over another section, which discussed "Present School Methods in Home Life," after which papers on education were contributed by Miss Hitching, Mr. D. O. Holme, and others. Dr. J. R. Kaye read a paper on "Ameliorative Measures Indicated by School Medical Inspection." Open-air schools came in for discussion, and Sir Charles A. Cameron of Dublin maintained that the meteorological conditions in Ireland were against their adoption. He urged strongly the need for medical inspection of school children in that country. On the following day Dr. Arthur Newsholme gave an address on Preventive Medicine, in the course of which he discussed alcoholism and the spread of enteric fever by shell-fish. Dr. E. F. Trevelyan spoke on the prevention of tuberculosis. The first paper in the Section for Child Study was by Mrs. H. Fisher, who discussed the value of voluntary effort in reducing infant mortality.

Degree Ceremonial at the University.

In connexion with the Congress a congregation of the University was held on July 19th, presided over by the Vice-Chancellor, for the purpose of conferring honorary degrees on Colonel T. W. Harding, Sir James Crichton-Browne, and Major Ronald Ross. Colonel Harding was presented by Professor Phillips in the following eloquent words :—

> I present to you for the degree of Doctor of Laws the President of the Health Congress now being [illegible] he has purchased with a great [illegible] Harding is a man so urbane tha[illegible] *urbanus* does not become *rustic*[illegible] amoenum habet. It is difficult, [illegible] a few sentences the public record of one who has ever had a broad [illegible] been a chief case of municipal government. Honoured by the King, by the corporation of this city and of the borough of Cambridge, he now is to be admitted by you as a graduate of the University of whose council he is already a member.

Professor A. S. Grünbaum, Dean of the Faculty of Medicine, then presented Sir James Crichton-Browne and Professor Ronald Ross. For the first he claimed the position of a pioneer in the treatment of the insane, saying that at the time when, now more than 40 years ago, Sir James Crichton-Browne initiated at the celebrated West Riding Asylum the systematic study of the pathology of insanity and of its therapeutic treatment such methods were unknown, the resulting conspicuous successes and discoveries being evidence of the efficiency of his youthful directorate during ten years. The stimulus to microscopical research, to [illegible] cerebral localisation, arose, he considered, with Sir James Crichton-Browne, while as one of the original editors of *Brain* his articles were distinguished by an admirable delineation of clinical histories and pathological findings in unique and truthful word-painting. Of Major Ronald Ross, Professor Grünbaum said : "Few of us realise that in India alone nearly five million lives are the annual tribute exacted by malarial fever. The task undertaken by Major Ross 15 years ago was therefore no mean one—to discover how malaria passed from man to man and how it might be stopped. The mere systematic examination of the whole of many hundreds of mosquitoes in itself is no small feat; to do so fruitlessly and in the face of long-drawn disappointment, yet with intuitive hope, patience, and consciousness of ultimate success, are characteristics of the true investigator, found only in those pioneers of knowledge of whom each century produces but a handful." Professor Grünbaum concluded his oration with some graceful remarks upon Major Ross's literary achievements.

July 20th.

WEST LONDON POST-GRADUATE COLLEGE.—Dr. Reginald Morton has been appointed lecturer on radiology at this college. The general vacation course will commence on Monday, August 9th, at the West London Hospital, Hammersmith-road, W.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Chair of Surgery in the University of Edinburgh.

THE election to this important chair was made this week, when Mr. H. Alexis Thomson, assistant surgeon to the Royal Infirmary, surgeon to the Deaconess Hospital, and lecturer in surgery in the School of Medicine, was appointed professor of surgery in the University of Edinburgh. The appointment, as invariably occurs in these circumstances, was the subject of a very keen competition for the support of the curators.

The Women Students of Medicine in Edinburgh.

The students of the Edinburgh School of Medicine for Women gave an At Home some evenings ago to meet and say good-bye to "the finals"—that is, to the students who had finished the final examination. There was a large and a gay gathering of the students and their friends. The lecturers of the school were also represented. The gathering was held in the Women Students' Union. The toast of "The Finals" was proposed by the Dean of the Women's School, Dr. William Russell, and was responded to by Miss Mary Low, M.A., who receives her medical degree at the graduation ceremonial on July 23rd.

Graduation Ceremony at the University of Glasgow.

The summer graduation in Medicine at the University of Glasgow took place last week. The Vice-Chancellor, Sir Donald MacAlister, presided, and conferred degrees in medicine on 73 graduates, of whom two were recipients of the degree of M.D. At the close of the ceremony Professor John Cleland, who is about to retire from his chair, delivered his valedictory address. In the course of his address, which dealt largely with the relation of environment and heredity, he took occasion to refer to the vexed question of vivisection. He pointed out that the physician's and surgeon's art is indeed a noble profession, but only when ennobled by nobility of purpose. Nobility of purpose was the most effective stimulant to study, as well as to the performance of the duty at the bedside, and it ennobled the whole acquisition of study of every description. Even vivisection, that bugbear of unbalanced minds and of many who love to be thought kind-hearted, and to think themselves so—vivisection was made noble by the enormous amount of suffering which it prevented, and which could only be prevented by the knowledge so gained and beyond our reach by any other means. Professor Cleland went on to say that he had noticed in his friends who were obliged to resort to vivisection that they had a most praiseworthy fondness not only for man but also for bird and beast. They loved not bird and beast the less, but man more than their detractors practically did. Vivisection was a work to be pursued in the teeth of inclination for attainment of purposes of the highest order. The control of inclination and the subjection of it to preference of a higher end was not only necessary for such repulsive work, but was essential for the attainment of excellence of any description. No more obviously pleasurable occupation could be imagined than that of the artist, and yet the artist who allowed himself to be the slave of his humours and his moods would never attain an enviable success. In the case of the medical profession how much more obvious it was that natural inclinations should be under complete control. No weakness was allowable in practice; its effects might amount to a crime at the expense of the patient. He pointed out here to those who had just graduated that not only had they had already to do many things with equanimity which were repulsive to their natural feelings, but while it would be their duty to cultivate all kindness to the sufferers who might come under their care and toward their friends, still they would always have to be on their guard to repress the desire to please, and to be firm in decisions which might appear to them even hard and cruel. He went on to say that errors of all sorts might arise where there was neither ignorance nor unworthy inclination, simply from want of strength of purpose. Here an element of uncontrollable circumstance came in. Resolution was a quality which, like every other feature, was largely dependent on heredity, and heredity was not of our own making. It was an "unearned increment." Our power over our will was limited, and there was truth in the remark of Spinoza that we say that our will is free when we fail to discern the factors which are acting on it. But for all that we had some such power, and, like every other faculty, the power was increased by exercise.

Death of Mr. William Whitelaw, M.D. Glasg., F.F.P.S. Glasg., D.P.H.

Dr. William Whitelaw, medical officer of health of Kirkintilloch, died suddenly at Crieff Hydropathic Establishment on July 20th. For some years he had been subject to heart trouble, and had gone to Crieff for a rest and change. Dr. Whitelaw was a native of the burgh, where he was born 73 years ago. He was a Fellow of the Faculty of Physicians and Surgeons of Glasgow and a Diplomate in Public Health. He held the position of health officer since 1877 and was also visiting physician at Broomhill and Lenzie Convalescent Homes.

The Opening of the Argyllshire Sanatorium.

This institution, a gift to the County of Argyll from Mr. and Mrs. Tom Bullough of Fasnacloich, was formally opened at Oban on July 13th. The sanatorium is situated on the summit of a hill just behind the town of Oban. The ground on which the buildings stand was formerly a residential property consisting of about nine acres of land surrounding a moderate-sized house. The grounds are beautifully laid out with walks, drives, and shrubberies. They contain a good deal of well-grown timber, mostly coniferous, and are surrounded by pine woods. Magnificent views are obtained at different parts of the enclosure, views of mountain and loch characteristically West Highland. The former dwelling-house has been utilised as an administrative block, and in addition to providing accommodation for the matron and staff has dining rooms for the use of patients. Accommodation for the patients is provided in three single-storeyed blocks, the largest of which is of the well-known "butterfly" design, but with this innovation, the roof is flat, accessible by means of a wide staircase, and at each extremity of the tricorn platform there is a shelter for the use of patients, where, screened from the wind, they can bask in the sun when it is too near the horizon to strike the lower parts of the building. Another block, situated between the last and the administrative buildings, is to be used for any patients that it may be thought advisable to segregate. The third block contains a row of single-bedded rooms opening into a substantial verandah, which runs the whole length of the building. This is to be reserved for paying patients. All the buildings are elegant in design, but there has been no undue extravagance in their construction. The entire cost of the ground, buildings, furnishings, and appliances has been borne by the donors, so that it is no small gift that the public have received. The sanatorium is to be rate-supported, and the beds, with the exception of those set apart for paying patients, have been allocated to the various local authorities in the county who have agreed to contribute to the standing charges. A large number of guests were invited to the opening ceremony. Maclachlan of Maclachlan presided, and was accompanied on the platform by Mr. and Mrs. Macdougall of Gallanach, Provost Maclachlan of Oban, Dr. R. W. Philip of Edinburgh, Dr. W. Leslie Mackenzie of the Scottish Local Government Board, Mr. Neil Gillies the architect, and others. After a few preliminary remarks by the chairman, a silver key was handed to Mrs. Macdougall, who then declared the sanatorium open. Pulmonary consumption is very prevalent in the West Highlands, having been apparently imported within comparatively recent times from Lowland towns. Probably there is no part of Great Britain more favourable for combating this scourge by natural and easily applied methods, so that Argyllshire is to be congratulated on having been enabled to take a definite step in the war against tuberculosis in very favourable circumstances.

July 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Insanity in Ireland.

THE gist of the fifty-eighth report of the Inspectors of Lunatics in Ireland may be summed up in two paragraphs:

(1) the number of the insane under care in Ireland has increased from 250 per 100,000 of the population in 1880 to 547 per 100,000 in 1908; and (2) the total number under care in January, 1909, was 23,931, as against 23,718 on the previous Jan. 1st. A comparative study of Irish lunacy statistics shows that for the past 18 years the number of lunatics in proportion to the population has increased by over 50 per cent., while for the past few years there is a lowering in the rate of increase. The average rate of increase for the entire period from 1880 to 1908 was over 10 per cent., while for the past three years it was only 5 per cent. The actual increase in 1908 was 213 cases, and in 1907 it was 164, but it must be clearly understood that the 213 additional cases in 1908 do not represent an actual increase, as the numerical increase is mainly the result of transfers to asylums of the inmates of imbecile wards of workhouses. One point has also to be noted, and that is that the figures with regard to the insane in asylums come short of the entire insane population of the country in respect of the fact that they do not include those who reside in their own houses or with relatives or are wandering at large. It is calculated that if by a general census of the entire population a trustworthy estimate of the insane in these classes was formed, it would amount to 15 per cent. of the total. When, however, all allowances have been made, the fact remains that there has been a marked increase in the number of the insane in Ireland.

Hospitals' Tuberculosis Committee.

At a special meeting of the committee held on July 16th, Sir John W. Moore being in the chair, the Countess of Aberdeen stated that recently in Canada and the United States she had had the opportunity of meeting a number of workers in the anti-tuberculosis campaign which was being carried on so actively in America. She had been invited to address several meetings in New York, Boston, and Detroit, with the special object of describing how the crusade was being conducted in Ireland under the auspices of the Women's National Health Association. Great interest was manifested in the movement, and the result has been the formation of committees in the cities above mentioned for the purpose of arousing sympathy amongst American citizens of Irish parentage and of obtaining their practical coöperation in assisting the work in Ireland. As a result Mr. Robert Collier had already promised Lady Aberdeen £1000 per annum for five years, with the object of equipping and starting a tuberculosis dispensary in the city of Dublin in memory of his late father, Mr. P. J. Collier, and to be called after him. It was agreed by the committee that the Dublin hospitals should be communicated with, with the object of obtaining their coöperation in the work of the proposed tuberculosis dispensary.

Inspection of South Dublin Dairies.

At the fortnightly meeting of the South Dublin rural district council, which was held on July 14th, a report was submitted by Mr. James D. Richardson, M.R.C.V.S., veterinary dairy inspector, who stated that he had inspected the cattle-sheds and dairies in the district during the months of April, May, and June, 1909, and had found all the cattle in the district healthy, and a great improvement in cleanliness. The ventilation in several of the sheds had been greatly improved, and the limewashing had been done in some cases since the cattle went to grass. Better attention had been paid to removing the manure. He had given instructions for some of the sheds to be raised where air-space was not sufficient and where overcrowding had taken place, and for imperfect drainage to be rectified. The report was marked "satisfactory," which we may certainly consider it to be.

The Pollution of Belfast Lough.

It is announced that the Royal Commission on Sewage Disposal has undertaken to investigate thoroughly the difficult sewage problem in Belfast, and that the Commissioners will pay a preliminary visit to that city next week for the purpose of making certain observations and arranging the lines on which their subsequent investigations will proceed. They will deal with the *ulva latissima* growth which causes the foul smell on the foreshores of Belfast Lough, and other matters concerning the state of the lough. At the present time, when the wind blows from the lough inwards on the land on either side a horrible smell arises, and silver articles in neighbouring houses are blackened by the sulphuretted hydrogen emitted by this seaweed. It is merely playing with the question to advise, as has been done, the removal of this plant; what is wanted is the removal or special treatment of the sewage on which it feeds and grows. At the present time Belfast Lough is a vast open sewer, receiving the sewage from a city with a population of over 370,000 people, only a mere fraction of this vast sewage material being in any way treated.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Operations on Diabetic Patients.

QUESTIONS connected with the performance of operations on diabetic patients recently engaged the attention of the Society of Paris Surgeons. M. Ozenne said that in a case of urgency he would operate on a diabetic patient even though there was a prospect of a fatal termination, but he would decline to interfere if there was no urgency, because it was impossible to foresee subsequent developments. It had been recommended that a diabetic patient should be kept under treatment for some time and that an operation should be performed where there were signs of improved health; there was some justification for this, but it was nevertheless known that operation wounds might aggravate the disease and the results could not be predicted. M. Verchère said that urgency was an essential condition for the performance of an operation on a diabetic patient. The causes of the severe symptoms which such patients might display after an operation were unknown. In the case of a man suffering from diabetes and gangrenous phlegmon of the scrotum an incision was made with the thermo-cautery at noon and he was dead in the evening, although his previous general condition had not led to any expectation of such a result. M. Verchère then quoted other cases of a like kind in support of his opinion. M. Paul Delbet said that he had operated on six patients with four recoveries. Speaking generally, he considered that operations might be performed on diabetic patients who bore up well under the disease, but not on those who were cachectic. He preferred general anæsthesia to local or spinal anæsthesia.

A Medical Lawsuit.

A Madame Koenig has sued Dr. Doyen in the Seine Tribunal for 30,000 francs damages on the plea that he operated on her unskilfully for spasmodic torticollis. The court accepted the expert evidence of Dr. Berger and Dr. Monod, and non-suited the plaintiff on the ground that Dr. Doyen had performed a proper operation.

Early Hydrarthrosis in Phlegmasia Alba Dolens.

At a meeting of the Obstetrical Society held on July 1st M. Brindeau said that hydrarthrosis of the knee, which was a common symptom of phlegmasia alba dolens, might appear at an earlier stage than usual and might then form an important diagnostic feature before the occurrence of the obvious signs of phlegmasia. He reported three cases in which the women complained only of pain in the groin and the calf of the leg; there was at that time neither œdema nor any indication of phlebitis, but the presence of hydrarthrosis led to the diagnosis of phlegmasia, the symptoms of which manifested themselves subsequently.

Faulty Positions in Articular Tuberculosis.

At a meeting of the Society of Paris Surgeons held on July 2nd M. Dupuy de Frenelle drew attention to the relation which abnormal positions of the limbs due to muscular contraction might have to Poncet's tuberculous rheumatism. He said th[illegible] a whole class of cases of subacu[illegible]lve the diagnosis of white [illegible] train in the adult. M. Judet said that in the absence of any disorder of the nervous system permanent muscular contraction taking effect either at the knee or at the hip-joint seemed in the child to be in relation with chronic arthritis which was almost always tuberculous; in the adult the question was more complex, and the observed cases of dry arthritis which have secondarily developed into white swelling seemed to support Poncet's ideas.

Remote Effect of an Operation for Spina Bifida.

At a meeting of the Surgical Society held on July 7th M. Walther showed a male patient upon whom he had four hours after birth operated for spina bifida in the region of the sacrum. The patient, who was now 18 years of age, physically well developed and very intelligent, had until two years ago suffered from incontinence of urine and fæces, but the incontinence of fæces then came to an end. At present M. Walther was endeavouring to train the young man to control his bladder, for he believed that the condition was really a pseudo-incontinence due to inattention (*incontinence par paresse*). The muscular coat of the bladder reacted very well to galvanic stimulation.

Parkinson's Disease.

At a meeting of the Neurological Society held on July 1st M. Alquier described (1) the lesions found on necropsy of five cases of Parkinson's disease (paralysis agitans); and (2) the results of parathyroid opotherapy in six cases of the same condition. The examination of the central nervous system showed the existence of small lacunæ of perivascular disintegration in the tegmentum of the bulb with a normal state of the neighbouring nucleated cells and a slight diffuse neuroglial proliferation in the bulb. The muscles exhibited atrophy and vacuolisation or fibrillar division of certain muscular bundles. Except in the case of one female patient, parathyroid opotherapy brought about a decided and durable improvement as regards the pains, sleeplessness, and rigidity.

Serum Treatment of Cerebro-spinal Meningitis.

At a meeting of the Société Médicale des Hôpitaux held on July 2nd M. Dopter of Val de Grâce, speaking on the subject of the treatment of cerebro-spinal meningitis with antimeningococcic serum, gave a *résumé* of the cases hitherto published, together with such unpublished cases as he had a knowledge of. His statistics were based on 196 cases of cerebro-spinal meningitis treated exclusively with the serum prepared by him at the Pasteur Institute. Among these 196 cases there were 31 deaths, or an aggregate mortality of 15·9 per cent., but deduction of 12 cases which were moribund when the injections were given left 184 cases with 19 deaths, or a corrected (*defalquée*) mortality of 10·3 per cent. This mortality was a remarkable contrast to that of the cases treated by the ordinary methods, the average mortality of the latter being 60 or 70 per cent. In the opinion of M. Dopter this considerable reduction of the death-rate was due to the special manner in which he immunised the horses. At the beginning of the epidemic the serum which was issued for therapeutic use was obtained by immunisation according to the German and American methods, but at a later stage he immunised his horses only with living cultures introduced into the veins. A comparison of the therapeutic activity of these two serums was altogether in favour of the new form. With the original serum an aggregate mortality of 18·18 per cent. and a corrected mortality of 11·47 per cent. were obtained, while with the new serum the corresponding figures were respectively 10·93 and 8·06 per cent. The new serum therefore appeared to be more efficacious than its predecessor.

July 21st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Committee on Tuberculosis.

THE German Central Committee on Tuberculosis held its annual meeting at Berlin on May 22nd, the Secretary of State for the Interior being in the chair. The report for the preceding year, which was read by Dr. Nietner of Berlin, the general secretary, stated that the committee had paid 165,000 marks (£8250) on behalf of sanatoriums and 50,000 marks (£2500) to the Robert Koch fund for the prevention of tuberculosis. During the year 52,000 patients received attention in the sanatoriums, the average duration of treatment being three months. In the spring of 1909 there were 99 public sanatoriums, 34 private sanatoriums, and 18 sanatoriums for children, in addition to 79 institutions reserved for suspected cases of tuberculosis, for scrofula, and for convalescent children. There were also 92 Walderholungsstatten, or places where the patients spend the day in the open air, returning home at night. The workmen's insurance institutions (Landesversicherungsanstalten) have up to the present time paid 83,000,000 marks (£4,150,000) for the treatment of tuberculous patients under the Workmen's Insurance Acts. Dr. Hamel presented a report on the prevalence of lupus in Germany, as shown by the collective investigation which was carried out as on Nov. 1st, 1908, at the instance of the Imperial Health Office. Some particulars relative to this investigation were given in THE LANCET of Nov. 7th, 1908, p. 1412. It was stated that 18,000 medical men, or 57 per cent. of the medical profession in Germany, had answered the questions contained in the inquiry forms; and that 11,354 cases of lupus were registered. The disease was apparently more frequent in Western and Southern Germany than in the east and north. In this respect there was a striking coincidence with the occurrence of pulmonary tuberculosis. It was found that on an average 68 per cent. of the patients belonged to the female sex, but during childhood the boys seemed to be more liable than the girls to contract the disease. Dr. Kirchner recommended that more efficacious measures should be taken against lupus. He advised that pamphlets on lupus, written in a popular style, should be distributed at the public vaccination stations and at the conscription offices, and that lectures on the subject should be delivered in the schools. He further proposed that inexpensive lodgings should be provided where patients coming from the country might reside during their treatment in town. Many of these patients did not require sanatorium accommodation, and yet it might be difficult for them to obtain rooms in ordinary hotels and boarding houses.

Health of the Navy.

The report on the health of the German navy, compiled by the medical department of the navy states that the number of sick has somewhat increased since last year, being 500 per 1000, as compared with 714·5 per 1000 in the British navy. The highest sick rate was recorded in East Africa, where 992·8 per 1000 of the men were on the sick list. The duration of treatment was on an average 18·3 days. The duration of sickness was on an average 8·5 days on board ship and 9·8 days on shore, but in the Kiautchou territory it was 15·3 days. The daily number of patients was 23·4 per 1000 on board ship and 28·9 per 1000 on shore. Of the recruits, 934 men—i.e., 23 per 1000 of the naval force—had to be discharged from the service at once, the majority of them for cardiac diseases. After a longer time of training 172 men—i.e., 4 per 1000—had to be discharged chiefly on account of diseases of the eyes, mental diseases, and cardiac diseases; 99 men were discharged as partially invalided, and 406 as completely invalided. Diseases of the heart and lungs continued to be the most frequent cause of invaliding, although the percentage of cardiac diseases had undergone a considerable diminution. Whilst in 1895 there were 5 per 1000 discharged from the service for cardiac diseases, this number had decreased to 2·46 during last year. There were 65 deaths, giving a mortality of 1·5 per 1000. These deaths included ten from tuberculosis, seven from septicæmia, five from appendicitis, and three each from scarlet fever, enteric fever, insolation, and malignant tumour respectively; there were 14 cases of suicide, three of them among officers.

Bilharzia Disease.

At a meeting of the Medical Society Dr. Pfister of Cairo and Dr. Goebel of Breslau communicated a paper on the Bilharzia Disease, which is so prevalent in Egypt. Dr. Pfister showed specimens of the parasite distomum hæmatobium. Dr. Goebel said that the disease was caused by the deposition of the eggs of the parasite within the vessels of the mucous membranes of the bladder, the intestine, and the female genital organs. In the bladder they caused cystitis with proliferation of epithelium. One case of polypus and a few cases of cancer and cancroids were observed in association with the disease. The infarction of the urethra produced by the eggs caused stricture with consecutive fistula of the urethra and swelling of the scrotum and the *perineum having the appearance of elephantiasis.* The same condition might be found within the ureter and the pelvis of the kidney. The prevalence of calculus in Egypt was also to some extent caused by this parasite. In the intestine the eggs deposited in the submucous tissue produced enteritis, polypi, and infiltrations of the mesocolon; in the vulva and vagina they caused sclerosis. The eggs might also be conveyed by the blood into the liver, the lungs, the spleen, the pancreas, and other viscera, and by the lymph-*stream into the mesenteric glands. In the discussion* Professor Orth showed microscopical specimens of a similar parasite prevalent in Japan, the schistosomum Japanicum, which was conveyed through the portal vein to the intestines, the lungs, and the brain.

July 19th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Professor Carlo Ruata.

BEARING a name long and honourably known to readers of THE LANCET, Dr. Ruata has just received from his students in the University of Perugia an attestation of their indebtedness to him as professor of materia medica—a post which he has held with steadily enhanced distinction for 25 years. At a jubilee meeting convened *ad hoc*, at which the Rector of the University, Professor Icilio Tarducci, who holds the chair of the Institutes of Roman Law, Dr. Giuseppe Bellucci, professor of chemistry and Dean of the Medical Faculty, and the President of the Umbrian Pharmaceutical Association represented the Senatus, the Medical Faculty, and the profession, two of the leading students, Signor Rosanna and Signor Peiro, opened the proceedings with an address, followed by the presentation of a beautifully illuminated parchment and a gold medal in testimony of the esteem and affection of pupils past and present. Other speeches ensued, the spokesmen being the Rector, the Dean of Faculty, and the Pharmaceutical President above named. Professor Ruata made a touching and effective reply, inspiring the audience (which included many of the non-academic public) with the hope that he will live to celebrate his golden jubilee in the seat of learning which, thanks to him and his colleagues, maintains so worthily the best traditions of the Umbrian school.

President Taft and the Italian Red Cross.

Another interesting acknowledgment of good service vouchsafed is that of the Croce Rossa Italiana, which has bestowed on the President of the United States its gold medal, with diploma of honour, in testimony of the prompt and effective assistance rendered in the Siculo-Calabrian cataclysm by the American Red Cross, over which Mr. Taft presides. The President, accepting these testimonials in the name of the American Red Cross, dwells not only on their artistic beauty but still more on the proof they afford of the humanitarian spirit which makes the "whole world kin" in presence of a dire calamity. In organisation and practical working both associations have not a little to learn from each other, while in the spirit that animates them and in the alacrity with which they set themselves to their humanitarian task they are honourably identical.

The Immoral Press.

The extent to which "the great sin of great cities" is impairing the virility of the Italian youth—shown, *inter alia*, in the physical degeneration that causes 40 per cent. of rejections at each periodical levy for the army—has at last aroused public opinion; and a petition, signed by 40,000 ladies and presented to Parliament, marks the beginning of active measures for the repression of the obscene literature, printed and pictorial, over which children of tender years and of both sexes may be seen gloating at every street corner in the centres of population. In acknowledging receipt of the petition, Members of Parliament of every shade of party were unanimous in condemning the provocations to lust and to premature indulgence in the marital privilege held out to Italian youth. One or two ultra-liberal doctrinaires indeed raised the objection that suppression by the State of literature of any kind is an interference with "liberty of the subject"—that plea which would arrest legislation against the adulteration of food or compulsory vaccination—but these protesters were heard without sympathy or support. Meanwhile, the true remedy lies, in the last resort, with the public itself, but for whose demand the pornographic caterer would have to stop his supply. It is, indeed, an ethnological distinction between the Latin and the Teutonic races that whereas the comic literature of [illegible] in nothing else but breach of [illegible] latter finds its material in [illegible] British *Punch*, for instance, teeming with mirth-provoking incident and illustration undepraved by any *double-entendre* or lascivious suggestion such as makes the beginning, the middle, and the end of its Italian or French counterparts.

"Maxima debetur puero reverentia,"

said the great Roman satirist, anticipated in that injunction by Horace who forsaw the main cause of the decline and *fall of the Empire in the infraction of the same.*

"Fecunda culpae secula nuptias
Primum inquinavêre et genus et domos,
Hoc fonte derivata clades
In patriam populumque fluxit."

The Weather.

Among the "mirabilia" of this "mirabilis annus," not the least striking or memorable has been the caprice, the vicissitudes of the weather and the consequent harm wrought to health and to agriculture. Here in Rome we are having autumn in midsummer, the temperature oscillating between 68° and 70° F., while in the Italian Switzerland the hotels are empty, and at Vallombroso the few who have ventured to occupy them have been sending down to Florence for their winter clothing. From the Julian Venetia in the north to the Abruzzi and Calabria in the south we hear of nothing but rainfall, taking the form of snow in the uplands, or violent hail-storms, or "burrasche" (tempests), culminating in "nubifragi" (water-spouts). The damage to the crops is appalling—whole vineyards destroyed, with rivers overflowing their banks and flooding the arable lowlands. Add to this a return of earthquake shocks on the Siculo-Calabrian littoral and some notion may be formed of the misery, present and future, of our sorely visited Italy.

July 16th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Public Instruction on Medical Subjects.

THE Board of Public Instruction on Medical Subjects of the American Medical Association reports that there are many difficulties in the way of organising a system of carrying out its objects in a judicious manner. The ordinary newspaper rejects articles which it is not allowed to revise, but the revision usually results in the elimination of the useful matter or the insertion of popular fads or suggestions which render the article worthless and oftentimes harmful. The plan of procedure for the present is to limit the subjects for popular articles to a few of the most important, such as enteric fever, diphtheria, variola, dysentery, gastro-enteritis of children, ophthalmia neonatorum, malaria, meningitis, tetanus, rabies, cholera, and yellow fever. These subjects have been selected chiefly because they belong to the general infectious diseases which are more or less prevalent throughout the United States. Popular articles on these subjects will be prepared, and as each article is completed will be put in pamphlet form and kept in stock in a properly organised bureau and be available for physicians all over the country. In the event of a local epidemic at any point, as of enteric fever or other infectious disease, these pamphlets may at once be dispatched to those districts and placed in the hands of the people through the agency of physicians or other channels of distribution. The Board also created an auxiliary body consisting of one representative from each State, and each member is required to ascertain all matters in his State which are proper subjects for popular discussion, and to supervise in a general way the methods of reaching and educating the people. All articles

WILLIAM BROWN, L.R.C.P. EDIN., F.R.C.S. EDIN., M.R.C.S. ENG.

Mr. William Brown died on July 14th at Edinburgh, where he had resided since his retirement last year from the office of medical officer of health of Carlisle after holding that position for 25 years. His death will be mourned by every intelligent inhabitant of the town for which he laboured for a quarter of a century. Carlisle owes much to him for the vast improvements which have taken place in its sanitary condition during that period, and which have made the town one of the healthiest in England. Mr. Brown received his medical education at the University of Edinburgh. He came to London in the year 1872, when he became a Member of the Royal College of Surgeons of England. In 1873 he became a Licentiate of the Royal College of Physicians of Edinburgh, and in 1880 a Fellow of the Royal College of Surgeons of Edinburgh. Shortly after qualification he was appointed house surgeon at the Cumberland Infirmary and subsequently assisted his elder brother, the late Mr. Robert Brown, in private practice in Carlisle. In 1883 he was appointed medical officer of health of Carlisle, and by his influence several insanitary private slaughter-houses were abolished and a public one erected in their place. This measure, together with the abolition of old ashpits and pigsties in the town, practically resulted in the extinction of a virulent form of typhoid fever which at one time was epidemic in Carlisle. He also made some original investigations with regard to tuberculosis, and the results of these investigations were embodied in the first report of the Royal Commission on Tuberculosis in 1897, while he instituted a systematic veterinary inspection of dairy cattle. When last year he retired from his office the corporation of the town appointed him consulting medical officer of health in recognition of his past services.

Mr. Brown was keenly interested in ophthalmology and for many years maintained a private dispensary where a large number of patients suffering from diseases of the eye were treated gratuitously. In 1886 he was appointed assistant surgeon on the staff of the Cumberland Infirmary, and he was for many years honorary surgeon to the Carlisle Dispensary. He was a Fellow of the Royal Microscopical Society and a vice-president of the Carlisle Microscopical Society. In addition to the very able reports which he presented to the corporation of Carlisle as medical officer of health his contributions to medical literature included articles to medical journals on an Outbreak of Milk Typhoid in Carlisle, Human and Bovine Tuberculosis in Carlisle, and Lesions in Bovine Tuberculosis, the latter of which he contributed to the Transactions of the British Congress on Tuberculosis in 1901. Mr. Brown leaves a widow and three daughters.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Boudet, formerly professor of clinical medicine in the University of Lyons and Associate of the Paris Academy of Medicine.—Dr. Justin Steer, professor of medicine in Washington University, St. Louis.

Medical News.

UNIVERSITY OF LEEDS.—At examinations held recently the following candidates were successful in the subjects indicated:—

EXAMINATIONS FOR THE DEGREES OF M.B., CH.B.

FIRST EXAMINATION.

Par[illegible] Butler, Charles Marsh Gozney,* H[illegible] Abram Sinson,* Herman Louis T[illegible] m Wright.*

SECOND EXAMINATION.

Part I., Anatomy and Physiology.—Y. Elliott.

Part II., Materia Medica and Pharmacy.—H. Angel, J. H. Blackburn, J. Ferguson, G. W. L. Kirk, F. H. Kitson, G. P. Mellis, J. C. Metcalfe, M. Peto, J. J. Pickles, S. Samuel, H. P. Shackleton, and H. W. Symons.

FINAL EXAMINATION.

Part I., Pathology and Bacteriology, Forensic Medicine and Toxicology, and Public Health.—C. S. Brown, J. P. Brown, J. B. Fisher, W. S. Hart, H. N. Ingham, J. B. T. Keswick, H. S. Raper, B. A. Slocombe, G. V. Stockdale, and N. S. Twist.

Part II., Medicine, Surgery, Obstetrics, and Therapeutics.—J. N. L. Thaseby (first-class honours), H. L. Flint (second-class honours), R. E. Smith (second-class honours), S. M. Hepworth, and W. Shaw.

Diploma in Public Health.—W. Carnes.

DIPLOMA IN DENTAL SURGERY.

Part I., Anatomy, Physiology, and Dental Anatomy and Physiology.—H. R. Bentley and C. F. Salt.

Part II., Surgery, Dental Surgery, Pathology and Bacteriology, and Operative Dental Surgery.—C. F. Salt and F. C. Wilson.

* These students have completed the examination.

UNIVERSITY OF DURHAM.—At examinations for the degree of Bachelor of Medicine held recently, the following candidates were successful:—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry, and Physics.—Eric Johnson and Lionel Everett Markham, College of Medicine, Newcastle-upon-Tyne; Roger Paul Ninnis, Guy's Hospital; and John Logan Pringle, Frank Blair Robson, James Stewart Soutter, and Gordon Stewart Woodman, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—George Albert Berkeley-Cole, Garfield Carse, Cyril Duncan, Idris David Evans, Robert Lacy Kitching, Reginald Arthur Hooper, Nora Murphy, Frederick John Nattrass, and Carinna Augusta Barry O'Neill, College of Medicine, Newcastle-upon-Tyne; Grace Winifred Pailthorpe, London School of Medicine for Women, and Evelyn Ritson, Arthur Sutcliffe, and Cedric Overton Shackleton, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—Walter Lessey, Edinburgh School of Medicine; Ivan Miller Pirrie, College of Medicine, Newcastle-upon-Tyne; and Felix Stephens Rood, M.R.C.S., L.R.C.P., University College, London.

Elementary Anatomy.—George Edward Stephenson, College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

[illegible] Sarah Louisa Green, Norman Hodgson, James Kerr, Francis James Lidderdale, John George Ogle, Charles O'Hagan, Lionel Glover Pearson, Fred Phillips, B.A., Thomas Copeland Storey, Eleanor Walkinshaw, and Samuel Knibb Young, College of Medicine, Newcastle-upon-Tyne.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At recent examinations held in Glasgow the following passed their respective examinations:—

First Examination.—Roland John Croxford, Glasgow; George Alexander Grandsoult, West Indies; John Vincent Duffy, Belfast; William Cowan Holburn, Cambuslang; William Bannatyne, Glasgow; Alexander Watson, Rutherglen; Robert Clark Craig, Renfrew; and James Williamson, Paisley.

Third Examination.—Haripado Chatterjee, India; William Wood Shorten, Cork; Morris William Rees, Glasgow; Leon Galdemar, India; John Boyd Michie, Glasgow; James M'Cusker, Neilston; John Miller Chrystie, Glasgow; Robert Henry Jones, Glasgow; Mau[illegible] William Edward Hopkins, Carn[illegible]

Final [illegible] iglas, Greenock; William Edward Hopkins, Carnarvon; William John Taugher, Canada; Angus Cameron Livingston, Glasgow; James Young, Paisley; Ernest Wardman Wilbourne, Nottingham; Patrick James Taaffe, Glasgow; William Browne, Belfast; Seringapatam Narasimba Sreenivasa Aiyengar, Mysore; George Munro MacLeod, Glasgow; Erachshaw Dinshaw Shroff, Bombay; and Shivnarain Rozdon, Simla.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. H. Reichenbach of Breslau has been appointed Extraordinary Professor of Hygiene.—*Clausenburg:* Dr. Josef Imre has been appointed Professor of Ophthalmology, in succession to Dr. Hóoz.—*Freiburg:* Dr. H. Bäumler, Professor of Special Pathology and Therapeutics and Director of the Medical Clinic, is about to retire at the close of the present session.—*Giessen:* Dr. Arthur Weber, Assistant to Professor Voit, has been recognised as *privat-docent* of Medicine.—*Halle:* Dr. Richard Freund, *privat-docent* of Midwifery and Gynæcology, has been granted the title of Professor.—*Kharkoff:* Dr. S. Grusdeff of St. Petersburg has been appointed Professor of Clinical Medicine.—*Munich:* Dr. R. Rössle, *privat-docent* of Pathological Anatomy, has been promoted to an Extraordinary Professorship.—*Strasburg:* Dr. O. Looss has been recognised as *privat-docent* of Odontology.

THE ROYAL DENTAL HOSPITAL.—The committee of management at its meeting on July 15th unanimously decided to invite Dr. Dudley W. Buxton to accept the lectureship founded to meet the regulations for future dental students by the Royal College of Surgeons of England.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on July 14th, Dr. Blandford, the President, being in the chair. 21 directors were present. The death of a member of the society was reported and seven new members were elected. The sum of £1255 was voted for paying the half yearly grants to the 48 widows and 13 orphans on the books of the society The widow of one of the members applied for relief, her husband, owing to ill health, having been unable to make any provision for his widow; a grant at the rate of £50 per annum was voted The society only grants relief to the widows and orphans of deceased members Membership is open to any registered medical practitioner who at the time of his election is resident within a 20 mile radius of Charing Cross The subscription is 2 guineas a year, or a member may become a life member by paying a sum fixed by the by laws of the society The invested funds now amount to over £100,000 Application forms for membership and full particulars may be obtained by applying to the secretary at the offices of the society, 11, Chandos street, Cavendish square, London, W The next election takes place on Oct 13th Application forms must reach the secretary on or before Sept 22nd

PUBLIC HEALTH IN JAMAICA —The last annual report of the Registrar General of Jamaica gives much statistical information relative to the social condition of the colony during the twelvemonth from April 1st, 1907, to March 31st, 1908 The last census was taken in 1891, and the use of estimated numbers for the total population and other bases of statistics has therefore been necessary for 17 years The estimated population of the island on March 31st, 1908, was 835,799 The proportional marriage, birth-, and death rates are calculated on a mean population of 834,012 estimated as on Sept 30th, 1907 The marriages registered in the year numbered 6251, being at the rate of 7 4 marriages per 1000 of the estimated population Of these marriages 21 were civil marriages, the remaining 6230 being solemnised by ministers of 17 different religious denominations A remarkable feature in connexion with this subject was the impulse given to matrimony by the terrible earthquake which devastated Kingston on Jan 14th, 1907 Since 1903 there had never been more than 988 marriages in any quarter of a year up to the end of the December quarter in 1906, but during the March and June quarters of 1907 the numbers rose to 2797 and 2319 respectively During the year under consideration there were 29,210 births, giving a birth rate of 35 0 per 1000, which is the lowest since 1886 87, when the rate was 34 7 per 1000 As usual, the illegitimacy rate was rather high when regarded from a European point of view, being 61 7 per 100 births, the lowest rate since the year 1896-97, when it was 61 1 per 100 In this respect the parish of St Andrew seems to be the most virtuous, having an illegitimacy rate of only 48 8 per 100, whereas the parish *of St Thomas is at the other extremity of the scale with* a rate of 70 5 per 100 The number of deaths registered during the year was 23,672, giving a death rate of 28 3 per 1000, which is the highest death rate recorded in the 30 years of registration The rate for the preceding year was 26 2 per 1000 Of the 23,672 deaths, 27 6 per cent were deaths of children under one year of age, and 44 5 per cent were deaths of children under five years of age With respect to the causes of death, the largest number under any detailed heading was 7422 tabulated as "ill defined and not specified causes" The deaths from specified causes included 252 from influenza, 223 from enteric fever, 1083 from diarrhœa, 635 from malarial fever, 4814 from undistinguished kinds of fever, 30 from leprosy, 30 from yaws, 167 from pulmonary tuberculosis, and 1284 entered under the heading of "phthisis (not otherwise defined)" No death from small pox was recorded

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION —The annual meeting and dinner of this association was held at the Garden Club, Imperial International Exhibition, on July 15th, Dr Richard Paramore, the President, being in the chair Dr Oliver, as the guest of the evening, proposed the toast of "The Brussels Medical Graduates' Association' In responding to this toast the honorary secretary, Dr Arthur G Haydon, said that during the past year considerable progress had been made The membership was increasing, particularly from the colonies Every one of the recommendations of the council of the association had been carried out by the University of Brussels He hoped to be able to organise the annual meeting and dinner next year in Brussels during the great Exhibition there of 1910 Dr Major Greenwood (honorary treasurer) and Dr W E Kirby (past President) also spoke The officers elected for the ensuing year were —President Dr Paramore Vice-President Mr A D Cowburn Honorary treasurer: Dr Greenwood *Honorary secretary* Dr Haydon

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Colour Tests in the Mercantile Marine

ON the motion of Lord MUSKERRY in the House of Lords, a return has been ordered showing the colour tests adopted by France, Germany, and the United States for the Mercantile Marine Services

Metropolitan Ambulances Bill

Sir WILLIAM COLLINS has obtained a second reading for the Metropolitan Ambulances Bill in the House of Commons It is hoped that when the Bill goes before a committee further steps may be taken to decide whether the *London County Council or the Metropolitan* Asylums Board will be the authority charged with the administration of the ambulances

Milk and Dairies (Scotland) Bill

The Scotch Office has promised to give favourable consideration to a number of amendments which are suggested to the Milk and Dairies (Scotland) Bill Lord PENTLAND the Secretary for Scotland received a deputation representing the corporation of Glasgow on July 16th and discussed with it points on which a strengthening of the provisions was desired The members of the deputation suggested that certain ambiguities should be removed from Clause 13 which forbids the keeping of diseased animals along with healthy They wanted to put a clear and effective check on the evasion of the Bill in regard to the disposal of tuberculous cows They also asked that the medical officer in urgent cases of an outbreak of infectious disease should be empowered to make an interim order stopping the supply of milk from a suspected *dairy* The corporation of Glasgow also desired to retain its powers under a local Act of dealing with the sale of milk from a farm or dairy at which infectious disease existed Lord PENTLAND promised to give these points his favourable consideration The deputation considered this reply satisfactory One of the members of the deputation was Dr A K CHALMERS the medical officer of health of Glasgow

municate forthwith the fac

which it was intended to send the animal. If the noble lord would look at the Bill he would see that the owner of the cow was practically prohibited from parting with the animal, and that seemed to him to be inconsistent with the subsection. Another point on which he wanted to comment was that the examination and inspection of milk and butter were not applied to similar articles coming from abroad. He would put down amendments dealing with this matter at a later stage. He also pointed out that the whole expense of the compensation for the slaughter of tuberculous cows would fall upon the ratepayers. It had been said upon good authority that there were 200,000 or 300,000 tuberculous cows in the country which would come within the Tuberculosis Order of the Board of Agriculture. The result of the legislation would be a heavy charge on the rates, and he hoped the Government would be in a position to make a reassuring statement on this matter.

The Earl of Crewe said that he was surprised at the Earl of Camperdown's computation of the number of cattle at 200,000 or 300,000 which would have to be slaughtered under the Bill as tuberculous. Did the noble earl mean that these cows would come under the tuberculin test or that they were cows which should be slaughtered because they were so emaciated by disease that their milk would be contaminated? He did not believe that the number of the latter class would reach the total mentioned by the noble earl.

The Earl of Camperdown said that the computation was not his own. There were, however, a large number of tuberculous cows in the country. Everyone connected with agriculture knew that tuberculosis was very prevalent among cattle.

The motion for the second reading was agreed to.

HOUSE OF COMMONS.

Thursday, July 15th.

Poor-law Medical Officers in Scotland.

Mr. Cathcart Wason asked the Lord Advocate whether he would grant a return relating to dismissals of Poor-law medical officers in Scotland and the trouble thereby entailed on the poor.—Mr. Ure replied: If my honourable friend will move for a return in how many and in what parishes during the past three years Poor-law medical officers in Scotland have vacated office and what period in each case has elapsed before the appointments have been permanently refilled the Government will offer no opposition.

Monday, July 19th.

Vaccination in London Casual Ward.

Mr. J. Ramsay Macdonald asked the President of the Local Government Board whether, on the night of July 13th, F. J. Wilson, after having been admitted to the City of London casual ward in Shoe-lane, was expelled because he refused to be vaccinated; whether such conduct was the rule at this ward; and whether the Local Government Board proposed to take any action on the matter.—Mr. Burns replied: I have made inquiry and I am informed that a man named James Wilson was admitted to the casual wards on the 13th inst., was vaccinated without any complaint being made by him, and was discharged from the casual wards after the usual regulation period. I understand that it has been the custom at these wards for some years for persons admitted to the casual wards to see the medical officer on admission, and that unless they object he vaccinates them if necessary. The acting master states that he has never known a casual pauper to be ordered out or ejected for refusing to be vaccinated.

Tuesday, July 20th.

Fees for Vaccination Certificates.

Mr. Tyson Wilson asked the Secretary of State for the Home Department whether, in view of the fact that some justices of the peace charged a fee for signing an exemption from vaccination certificate, and that no fee was charged by others, he would, with the object of securing uniformity in the administration of the Vaccination Act, 1907, by circular or other means, inform the magistrates that they were not justified in charging a fee unless the services of the justices' clerk were utilised.—Mr. Gladstone (by written answer) replied: If the honourable Member will inform me of any cases in which justices have charged a fee for anything done by them in their magisterial capacity I will communicate with them. I do not, however, think that a general circular is called for, as I have no doubt that justices generally are properly informed on this subject.

Medical Examination of Postmen.

Sir William Collins asked the Postmaster-General whether, in connexion with the employment of postmen on cycling duties, any additional duties in regard to medical examination of postmen to be so employed had been placed upon medical officers; and whether he would state what regulations the Post Office had laid down in regard to such examinations.—Mr. Buxton wrote in reply: It has for some time past been a part of the duty of Post Office medical officers to examine postmen about to be employed on cycling duty. I have recently seen cause to extend this examination to men already employed on cycling duty, and to cause it to be repeated at intervals of four years. In order to ensure a searching and complete examination, a list of questions has been compiled for the use of medical officers, indicating those points which are of importance in the interest of the staff and of the public service.

Wednesday July 21st.

Germ-carriers in the Army.

Captain Clive asked the Secretary of State for War whether, seeing that treatment both with general and specific vaccine was now admitted to have failed, he could say when the supposed germ-carriers at Milbank Hospital would be released; and what compensation would be given them for detention, loss of promotion, &c.—Mr. Haldane replied: Although the general and specific vaccines have not been successful in the urinary cases, another method of treatment is now being employed, and it is not proposed to discharge these men as medically unfit until every reasonable method of treatment has been tried. I may point out that these men are undergoing this special treatment in their own interests and in the interests of their comrades to whom, in their present state, they would be considered a danger. No question of compensation arises.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institut and others possessing information suitable for this column, invited to forward to The Lancet *Office, directed to the S Editor, not later than 9 o'clock on the Thursday morning of e week, such information for gratuitous publication.*

Bhuttacharji, J. C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has b appointed District Medical Officer and Public Vaccinator for Lutterworth Union, Leicestershire.

Brown, D. W., M.D., M.Ch. Edin., has been appointed Certify Surgeon under the Factory and Workshop Act for the Pre (West) District of the county of Lancaster.

Browne, F. J., M.B., B.Ch. Aberd., has been appointed Certify Surgeon under the Factory and Workshop Act for the Abertil District of the county of Monmouth.

Dingle, H., L.R.C.P. Lond., M.R.C.S., has been appointed Certify Surgeon under the Factory and Workshop Act for the Barmo District of the county of Merioneth.

Griffith, William, M.B., Ch.B. Vict., M.R.C.P. Lond., has been pointed Assistant Physician to St. John's Hospital for Disease the Skin.

James, R. R., F.R.C.S., has been appointed Assistant Ophthalmic S geon to St. George's Hospital.

Mayne, John FitzGerald, M.B., Ch.B. Edin., has been appoin Senior Resident Surgeon at Oldham Infirmary.

McBride, C. A., M.D., C.M. Tor., L.R.C.P., L.R.C.S. Edin., has b appointed Casualty Officer to St. John's Hospital for Diseases of Skin.

Wood, T., M.D., C.M. Edin., has been appointed Certifying Surg under the Factory and Workshop Act for the Leith District of county of Edinburgh.

Woodcock, Louisa, M.D., B.S. Lond., has been appointed Clin Assistant to St. John's Hospital for Diseases of the Skin.

Vacancies.

For further information regarding each vacancy reference should made to the advertisement (see Index).

Birmingham, University of.—Chair of Zoology. Salary £600 annum.

Births, Marriages, and Deaths.

BIRTHS.

Aitchison.—On July 18th, at Drayton-terrace, S.W., the wife of Charles U. Aitchison, M.D., of a son.

[illegible] of William [illegible] of J. Alison

Highet.—At Bangkok, Siam, on the 16th inst., the wife (*née* Emma Robinon) of H. Campbell Highet, M.D., D.P.H., Principal Medical Officer, Local Government, of a son.

Newman.—On July 15th, at Windhill, Bishop's Stortford, the wife of J. C. Newman, F.R.C.S., of a daughter.

Smith.—On July 14th, at Cleveleys, Redbourne-avenue, Church End, Finchley, the wife of Thomas Smith, M.R.C.S., L.R.C.P., of a son.

Street.—On July 17th, at Cranfield, Woburn Sands, Beds., the wife of Albert Ernest Street, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

Woolley.—On July 12th, at Claremont-road, Surbiton, the wife of Edward J. Woolley, M.D., of a son.

MARRIAGES.

Ain[illegible]

DEATHS.

Batten.—On the 15th July, 1909, at Brunswick square, Gloucester, Rayner Winterbotham Batten, M.D. Lond., F.R.C.P., in his 75th year.

Brown.—At the Edinburgh Hydropathic, Craiglockhart, on the 14th inst., William Brown, F.R.C.S.E., Consulting Medical Officer of Health for the City of Carlisle.

Hartley.—On July 15th, at Bishop's Stortford, Charles Hartley, M.R.C.S., aged 60 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL HEROES OF ITALY'S "RISORGIMENTO."

For more than a month the Italian kingdom has been celebrating the jubilee of her "*Risorgimento*" (political resurrection), and, quite regardless of the wounded *amour propre* of her Austrian "consorella" in the Triple Alliance, nay, with an effusive delight in the commemo-[illegible] her sons in the [illegible] drove the hated [illegible] hich never rested till, from its perch on the Capitol, it looked down on an Italy free and united from the Alps to Etna. A conspicuous place of honour in that mighty movement she has reserved for her medical sons, whose deeds of heroism in ambulance and hospital, nay, on the stricken *field itself*, are for all time engraven on her heart—

"Monumentum aere perennius."

If, according to Carlyle, Mazzini sacrificed to the Revolution one of the very finest literary faculties of the nineteenth century, not less true is it that Agostino Bertani devoted to the medico-military service of the patriotic arms a genius for surgery which, in the "cloistered calm" of the University clinique, might have fructified in professional conquests, surpassing even those of his master Panizza, or of Panizza's master Scarpa *Even in the few years allotted to him* after the fall of the Temporal Power and the consummation of his country's ideal Bertani gave proof of his hygienic sagacity and initiative in his masterly "Codice Sanitario," which, to her inestimable profit, Italy is steadily utilising in city and in commune. A Milanese by birth, though of Mantuan *origin, he was one of a phalanx of medical men to whom a grateful* country has just dedicated a commemorative "immortelle"—an album issued by the "Milano Sanitario" to preserve the names of those surgeons and physicians of Lombard, and more especially of Milanese, parentage who gave up their *lives and future prospects to the cause of the motherland.* But for this memorial young Italy would be ignorant of the personality and career of many a brilliant graduate in medicine whose work in the improvised hospital or on the battlefield under fire was as unselfish as it was effective—recognising no distinction between Italian, French, or Austrian among the wounded, and only suspended by the collapse of the worker himself, succumbing to fatigue when not the victim of a hostile bullet. Some notion of that work may be formed when we read that in Milan alone from June 6th to July 31st, 1859, there were under treatment 25,568 sick and wounded from the *battlefield*, including 14,641 French, 3790 Italians, and 7137 Austrians—not *forgetting the fact that on June 5th there* were already in the various hospitals of Milan 2066 local patients. Of the soldiers who left the wards "cured" or transferred in convalescence to other resorts, there were 10,399 French, 391 Italians, and 5935 Austrians; while there died 1591 in all—that is, 815 French, 31 Italians, and 745 Austrians. Still surviving among the Milanese surgeons who took part in this service, many of them, happily, still active for the public good, are the Cavaliere Dr. Ferdinando Calderini, colonel of the reserve; Dr. Malachia de Cristoforis, senator of the kingdom; the Cavaliere Dr. Felice dell' Acqua, emeritus physician-in chief *to the municipality; the Commendatore Dr. Rocco Gritti, emeritus* head physician of the Ospedale Maggiore; Dr. Paolo Mantegazza, senator of the kingdom, professor of anthropology in the Istituto de' Studi Superiori in Florence, Dr Amilcare Ricordi; Dr. Emilio Sozzani; the Cavaliere Achille Visconti, emeritus clinician-in chief of the Ospedale Maggiore; and the Commendatore Giuseppe Candiani, pharmaceutical chemist and founder and president of the Casa dei Veterani *of Turate.* "*We have made Italy,*" said Cavour's successor Massimo D'Azeglio in 1860; "we have now to make Italians!" Of that second creation Italy need never despair if only she remain true to her nobler traditions and follow in the steps of those practitioners of the healing art who, dead or still surviving, contributed so effectively to her "Risorgimento," political and social, scientific and professional.

THE TRUTH ABOUT ST. HELENA AS A HEALTH AND HOLIDAY RESORT.

In a recent official report to the Colonial Office the Governor of *St. Helena (Lieutenant-Colonel H. L. Gallwey, C.M.G.)* has thought it advisable to deprecate what he considers the exaggerated claims put forward by injudicious well wishers in regard to the supposed advantages of the island as a holiday resort. The most alluring inducements, observes Colonel Gallwey, are being held out by these people through the columns of the English newspapers as to St. Helena's advantages. Among those claimed are a splendid climate, cheap *hotels* and *boarding houses*, comfortable houses at a low rent, and so on. They even go so far as to state that St. Helena possesses some of the finest golf links in the world. The kindness which *prompts St. Helena's* well-wishers in England to promote the colony's interests is fully appreciated, but it is generally recognised that more harm than good must result from misrepresentation, which can only lead to disappointment among any persons who might decide to visit the colony on the strength of such unwarranted inducements. It would serve the island's interests better if only facts were stated. These facts are that the climate is very healthy, and, although in the tropics, that of the highlands is very temperate and never too hot. There is not a single hotel in the island, and the so-called boarding-houses in Jamestown might at a pinch accommodate half a dozen people. There are no boarding-houses in the country, where visitors would require accommodation. There are about six untenanted houses which could be leased at reasonable rents, half of which are either unfurnished or only partly furnished. "Some of the finest golf links in the world" must be taken as referring to the one golf course of nine holes, there being no suitable site for a second course in the island. His Excellency is of the opinion that if visitors were forthcoming boarding-houses would soon spring up. It is not to be expected, however, that such establishments will be started on chance. As things stand at present, accommodation for more than a very few visitors does not exist, and any persons proposing to visit the colony would be wise to ensure beforehand that the accommodation they require is both suitable and available. Visitors, too, must be prepared to find the island somewhat dull. There are few diversions by day and practically none by night. Taking it all round, the island's advantages, as far as holiday and health seekers are concerned, lie almost entirely in its healthy climate. This estimate of the island is in the Governor's own words, and we think it well to repeat his warning.

THE SALE OF FOOD AND DRUGS ACT AT BRISTOL.

We have received a copy of the report of the public analyst and bacteriologist of the city and county of Bristol (Mr. Edward Russell, B.Sc., F.I.C.) for the year ending Dec. 31st, 1908. The report is divided into three sections: (1) Food and drugs work; (2) bacteriology; and (3) miscellaneous analyses. The bacteriological section refers for the most part to pathological work undertaken in connexion with cases of diphtheria, tubercle, and enteric fever. There are, however, recorded some special inquiries, amongst which attention is given to the straining cloth used by milkmen and to cream, both of which gave evidence of bacillus coli. The number of examinations made in this section was 5764. Under the Food and Drugs Acts 1303 samples were examined. The figures show a slight increase in the adulteration rate in Bristol, which is contributed chiefly by milk. Out of 101 samples, of which 36 proved to be watered, 64 samples were found to be deficient in fat. As regards preservatives, the use of salicylic acid in several samples of aerated beverages is noted.

THE COMPLETE ANTIVIVISECTIONIST.

The following letter from Sir George W. Kekewich addressed to the editor of the *Daily News* appeared in the issue of that paper for July 17th, under the heading "Doctors and Vivisection."

> Sir,—In a recent issue of the *Daily News* there appears a letter from a Mr. Porter, of St. Luke's Hospital for the Insane, who says that at the anti-vivisection meeting in Hyde Park on Saturday last he challenged a statement of mine to the effect that vivisection made medical men callous, and that they experimented on persons in hospitals, who, of course, usually belong to the working class. He challenged it, according to the newspapers, by calling upon me to substantiate my dirty, blackguardly lies—he states in his letter in milder language that I was unable to substantiate my "statement" by evidence. He now asks for facts.
>
> Sir, I am not going to fall into that trap; names and places would mean actions for libel, backed by most of the medical profession. But it is matter of common knowledge that such things as I mentioned do take place, though of course infrequently. I do not wish it to be understood that I make any accusation of the kind against the great mass of men in one of the most arduous and honourable of professions.
>
> If Mr. Porter desires evidence, I may, however, refer him to a pamphlet entitled "Human Vivisection: A Statement and an Enquiry," published at Chicago, U.S.A., by the American Humane Association, of 560, Wabash-avenue.
>
> He will there find ample evidence that the statement I made is founded on fact.
>
> Yours &c.,
>
> G. W. KEKEWICH.

We will leave this effusion to speak for itself, only reminding our readers of the famous lawsuit of Bayliss *v.* Coleridge, a case in which a judge and jury were asked to examine a specific charge of cruelty made against a scientific investigator by an opponent of humanitarian progress. We would add that agitators, to command success, need courage as well as wind.

THE MEDICAL MISSION AUXILIARY.

Mercy and Truth, the official organ of the Medical Mission Auxiliary of the Church Missionary Society, in its issue for July contains, in addition to the usual reports from the various foreign stations, the annual report of the work of the auxiliary during the year 1908-09. The value of medical mission work is now generally admitted, though medical missions do not receive the financial support which they undoubtedly deserve. Although the Medical Mission Auxiliary is able to report an increase in its receipts and a balance of £3707 after the payment of expenses, it is with regret that we notice that this balance has to be accounted for "by reductions imposed upon the missionaries in the field." Men who risk their lives in the service of humanity in unhealthy foreign climates should receive the most generous treatment from those who send them forth in the name of charity. The difficulties and hardships of medical missionary life can scarcely be realised by those whose knowledge is obtained from annual reports and lectures, or the work would be more heartily supported. The cost of supporting a bed in a Church Missionary Society's hospital in India, Persia, Palestine, or Egypt is £10 per annum; in China or East Africa, £5. Cheques should be crossed and made payable to Mr. R. Maconachie, Church Missionary House, Salisbury-square, London, E.C.

COMPENSATION FOR A KELOID.

In the City of London Court on July 19th, before Judge Lumley Smith, K.C., a boy, 15 years old, sued the Great Eastern London Motor Omnibus Company, Limited, to recover damages for an unusual cause. It appeared that as he was crossing King William-street one of the defendants' motor omnibuses, going, it was said, at a "most reckless pace," struck him to the ground. It dragged him a considerable distance, and his leg was injured. The boy was taken to Guy's Hospital, where he was detained for many weeks, and treated by skin grafting. This, however, was not successful, and keloid had supervened; the boy's knee was contracted, and it was feared that he would never be able again to follow any occupation because of the keloid condition. Medical evidence was given that the plaintiff's disease was incurable and that it might be tuberculosis. Nobody really knew what keloid was. Two medical men, called for the defence, admitted that the disease was not curable; but they considered that the plaintiff's condition was not so serious as had been depicted. Ultimately the plaintiff agreed to accept £75 as compensation.

"INFORMING THE POLICE."

Mr. G. F. Roumieu, the coroner for West Surrey, had something to say at a recent inquest, near Godalming, on the question of medical men giving information to the police. The case was one in which a servant girl had wilfully poisoned herself. A medical man was called in and attended the girl until her death 12 hours after she had taken the poison, of which event the lady of the house informed the police nine hours later. The coroner said that he believed there was a strong feeling in the medical profession against giving information to the police, but there was a common law obligation upon every citizen in such circumstances to inform the police, whose duty it was to inform the coroner. If a person attempted to take his life it was an offence, a common law misdemeanour, whether the attempt was successful or not, and the police ought to be informed. In the event of a person dying this was obligatory. The police should be informed as quickly as possible in such cases, because it was their duty before anything was moved to take the evidence as to the surrounding conditions and everything that might throw light upon the death. In this particular instance no blame attaches to the medical man, who ceased his attendance on a trying case after midnight, because he omitted to call on the police before proceeding home, and doubtless the whole household was too upset by the occurrence to take the proper steps at once. But it is well for medical men to bear in mind that in such cases the police must be informed promptly, especially as in such tragic situations the medical attendant is often the man to whom friends or relatives turn for immediate guidance beyond the actual treatment of the patient.

AN INCORRIGIBLE PARENT.

In an annotation last week we reported the death of an infant at Brighton from overlying by a notoriously drunken mother. We learn that the woman was again brought before the Brighton magistrates on July 19th—nine days after the proceedings in the coroner's court—charged with being drunk while in charge of a child aged three years and four months. The magistrates probably had not forgotten the proceedings before the coroner's court on July 10th, the woman's first appearance at the police-court only a few days before the child's death on the charge of neglecting her children, nor her record of eight previous convictions—several for a similar offence. On this occasion a policeman found the woman leaning against a wall at half-past ten in the morning in such a condition of drunkenness as to be quite incapable of taking care of the child she had with her. It is satisfactory to note that the magistrates realised the seriousness of the offence in this case, and sentenced the woman to one month's hard labour. But considering all the circumstances the sentence does not err on the side of severity.

◆

Fairplay.—We cannot express any opinion as to the legality of such proxies, but we are clear that the request for them should never have been sent out. The rules of the government of the infirmary are intended to provide equal chances to all competitors for a vacant post, and the use of private information to secure premature support for one candidate cannot be approved of. Canvassing appears not to be forbidden by the rules, and the amount to which it is employed must be left to individual taste. The probability is that the General Medical Council would not consider the matter one suitable for their notice.

Mr. W. G. Walford is thanked for his interesting communication.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1909, which was completed with the issue of June 26th, and the Title-page to the volume, were given in THE LANCET of July 3rd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1909 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Presidential Address

ON

THE BELFAST MEDICAL SCHOOL: A SURVEY OF THE STATE OF MEDICAL EDUCATION: NECESSARY REFORMS AND THE QUEEN'S UNIVERSITY OF BELFAST.

Delivered at the Seventy-seventh Annual Meeting of the British Medical Association

BY SIR WILLIAM WHITLA, M.D. R.U.I., LL.D. GLASG.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, QUEEN'S COLLEGE, BELFAST.

YOUR EXCELLENCIES, LADIES, AND GENTLEMEN,—I discharge my first duty, and that which lies nearest to my heart, when I thank the members of the British Medical Association for the honour which they have conferred upon me by electing me to the presidential chair of their great society, numbering over 20,000 members, and containing in its ranks all that is best in the medicine of to-day, not only in the British Isles but in our great colonies and dependencies beyond the seas.

It is my pleasing duty to offer, upon behalf both of the members of the medical profession residing in and around Belfast and in the Province of Ulster, a hearty Irish welcome to our visitors, and this greeting is most cordially endorsed by our citizens and chief magistrate, who have honoured us by their presence to-night at this our seventy-seventh annual meeting.

Our worthy and public-spirited Lord Mayor and city council have given practical proof of the sincerity of their welcome by generously placing at our disposal their Exhibition and Ulster halls and their Botanical Gardens, as our esteemed Vice-Chancellor and his professors have thrown open to us for the week the entire range of class-rooms and buildings in the University.

MR. SIMEON SNELL.

My next duty is a sad one, as I refer to the irreparable loss sustained by the Association in the death of Professor Simeon Snell of Sheffield, who departed this life on April 17th last, during his year of office as President. Little did any of us, except, perhaps, his immediate circle of friends, suspect, when admiring his genial and manly presence at the highly successful Sheffield meeting a brief year ago, that never again were we to be privileged to sit under the spell of his magnetic personality. The exhaustive sketch of his strenuous life which appeared in our Journal soon after his death [illegible] about the high position which he [illegible] neverthe- [illegible] mourn for him, and to pay [illegible] need of a melodious tear." His whole life was a long series of brave and strenuous efforts to make his profession better than he found it, to improve the condition of his fellows, and to exalt the position of the city in which his lot was cast. The cause of his death, which occurred at the comparatively early age of 56 years, was arterio-sclerosis, and, as remarked by his friend, Sir Anderson Critchett, "had he been less prodigal of his boundless energy we might perhaps have been spared his untimely loss, but his faculties were ever at concert pitch, and he seemed to realise to the full Elizabeth Barrett Browning's terse and forcible injunction, 'Get work; be sure 'tis better than that you work to get.'" This continuous draft upon his capacity for work led to the inevitable result—

> "Comes the blind Fury with th' abhorred shears,
> And slits the thin spun life. 'But not the praise.'"

But not the praise—since he faded from our sight, wearing the laurel crown of our great Association.

THE GROWTH OF BELFAST.

I shall not pause to dwell, as is usual on such occasions, upon the ancient historical associations of the city which the m[illegible] by their visit. Our [illegible] his "History of Belfas[illegible] "Belfast as a [illegible] offers a marked contrast in this [illegible] hich the annual meetings of the [illegible] held in England where the histor[illegible] often in miniature the history of [illegible] iseless to deplore as it woul[illegible] it in—nevertheless has not [illegible] effect upon individual and [illegible] the sturdy citizen of Belfas[illegible] not boast a gen'rous race." [illegible] thoroughly he has learned the lesson if you survey our busy wharves with their evidences of a flourishing world-wide commerce, as you see the stately leviathans which glide down to the sea from our *shipbuilding yards, and as you catch a glimpse* of the myriads of human spiders who spin and weave from morn till night in our great flax mills and linen factories.

I shall not weary [illegible] the almost unparalle[illegible] made by Belfast in [illegible] you that since the Association honoured the city by its first visit, just a quarter of a century ago, the population has almost doubled and is still making rapid strides, which in a few more years promise to reach the grand total of half a million souls. At the same time it is a source of honest pride to the thoughtful Belfast man that whilst his native city has been directly prospering by his energy during the last three or four decades the achievements which have brought this success to her have in some instances purchased far-reaching benefits to many parts of the habitable globe. We have only to reflect upon the perfection of the processes employed in the spinning and weaving of linen, and the epoch-marking innovations in naval architecture inaugurated in 1870 by Sir Edward Harland, [illegible] applied and perfected by his [illegible] yard which it will be your privil[illegible] week. The development of these new principles may in a sense be regarded as having annihilated sea distance, knitting together all parts of our huge empire, and bringing within comparatively easy reach the far-away places of the world. Neither do we forget the important part played in this triumph over storm and wave by our illustrious townsman, Lord Kelvin, who by his perfection of the mariner's compass has laid mankind under lasting obligations to his genius.

I shall refer to but one other invention of comparatively recent birth in Belfast. The application of the pneumatic principle to vehicular tyres by our townsman has in a similar sense anniliated land distance. Without its aid the motor-car (in which so many of you now speed upon the wings of the wind on your errands of mercy) would have been an impossibility. The indirect outcome of the use of the Dunlop tyre has been the planting of flourishing industries in many English and continental centres, as it has already covered with rubber trees the slopes of Ceylon and the swamps of the Malay Peninsula, whilst its direct effect has been the establishment of a revolution in human intercourse. From this remarkable invention Belfast as a city has, however, only reaped the benefits which have been enjoyed by all parts of the civilised world owing to the headquarters of the industry being established in Coventry.

The present visit of the British Medical Association coincides with an epoch in our progress and history far more important and wide-reaching than those to which I have just referred. You do not find us gathered round the stocks to witness the launch of a huge record-breaking ocean liner, or watching the gradual evolution of a pneumatic tyre, but you discover us in the act of taking the first steps in the inauguration of a movement compared with which all other of our past achievements are to be considered as of minor importance. You see us gathered around the cradle of an infant university confronted by potentialities beyond the power of language to describe or of human thought to foreshadow.

THE NEW UNIVERSITY.

The problem of higher education presents at all times to the thoughtful mind a fascinating study, but on its purely literary and scientific aspects the present is not the occasion to dwell. The birth of a university brings at once to the mind of the medical man the serious consideration of the examination standards by which the new portal to the profession is to be guarded, and also the still more vital subject of the efficiency of the training and teaching to be carried out under its direct supervision. To the layman the event is of still greater importance; the medical student of to-day becomes the physician or surgeon of to-morrow, armed with his lifelong commission in the struggle for the relief of suffering and the prevention or cure of disease, and in his hands are often placed the issues of life and death. For these reasons every member of the community becomes interested in or involved more or less at some period of his existence in the efficiency of the institution which has presided over the training of his medical attendant. Hence no pains should be spared by the municipality or by the State to make this training as perfect as possible. Many people are apt to think, if they think at all, that the recognition of the medical man as a valuable public or national asset is an idea of modern growth, but you all remember that stirring episode in the *Iliad*, where Homer 3000 years ago makes Idomeneus exclaim, when commanding Nestor in the din of battle to fly to the relief of the wounded leech, Machaon, "when trembling Greece for her physician, feared":

> "Ascend thy chariot, haste with speed away;
> A wise physician, skilled our wounds to heal,
> Is more than armies to the public weal."

It behoves us as medical men periodically to review our position as regards the teaching and practical training of those desirous of joining our ranks, and upon an occasion like the present no more suitable subject could occupy our attention than a survey of the existing conditions of medical education, and a scrutiny of the requirements and modifications of these methods necessitated by the progressive march of scientific research as knowledge grows from more to more. I am confident that such a survey will also incidentally reveal evidence to satisfy the medical profession, as represented by this great Association, that our new university is fully alive to its serious responsibilities, and will be able to maintain the efficiency and to uphold the dignity of medicine in this portion of His Majesty's dominions.

THE HISTORY OF THE BELFAST MEDICAL SCHOOL.

The early history of medical teaching in any educational centre is closely identified with the growth of the facilities afforded by hospital accommodation. The first mention of any such institution in Belfast, according to the testimony of Dr. Malcolm, who more than half a century ago wrote the annals of the old General Hospital, is to be found in the appalling statement that in 1689 an epidemic raged throughout the north of Ireland, thousands of the stricken being crowded into "the great hospital at Belfast," which in the course of six months became the grave of 3762 victims. This institution was evidently a temporary one, and probably under military control, since no further mention is found of any form of organised medical relief till the inauguration of the Belfast Charitable Society three-quarters of a century later, followed in 1792 by the establishment of the Belfast dispensary system, and a few years later by the erection of the lying-in hospital and the creation of a fever hospital, the first institution of the kind established in Ireland.

The old General Hospital, which still stands in Frederick-street, was commenced in 1815 and opened in 1817, in the midst of a terrible epidemic of typhus, the victims being carried into the new buildings, whose freshly plastered walls were still dripping with moisture, and whose stairways had been scarcely rendered secure by the overworked carpenters and masons. During the first three years of its existence no fewer than 3527 patients were admitted within its walls. Malcolm dwells with pride upon this period of our local history, when he states that "Belfast presented a glorious spectacle of philanthropy deserving the admiration of the world. The prosperity of her later years is doubly blessed by the reflection that when but in the infancy of her strength she drained her dearest resources to help the desolate and afflicted, to dry the orphans' and the widows' tears, to feed the hungry and clothe the naked, and rescue a myriad host from impending destruction." It was during such a period of storm and stress that we learn of the first beginnings of the Belfast Medical School, when, in 1820, at the termination of the epidemic which had stricken one-fourth of the entire population, pupils were first admitted into the wards of the hospital to study disease at the bedside and to act as clinical clerks and dressers, in accordance with a resolution passed by the committee in 1817, just before the outbreak of the pestilence. (My auditors will therefore observe that in a few years hence the Belfast Medical School will be celebrating the first centenary of its existence.) This decision was the immediate outcome of the enlightened spirit which stimulated the founders of the charity when they deposited in the first stone, laid in 1815, the inscription dedicating the building to the advancement of medical science and the relief of suffering:

HOC NOSOCOMION
AEGROTIS ET ARTI MEDICAE
SACRUM.
IN SALUTEM PUBLICAM (ETC).

Not content with the mere admission of students to watch the practice of the medical staff in the wards, we find in 1826 that the committee were fully alive to their responsibilities, realising that clinical instruction must be for all time an obligatory portion of the duties of the physicians and surgeons. Accordingly, a systematic course of clinical lectures was commenced in the following summer, and these were most scrupulously persevered with, the lectures being delivered in the theatre of the hospital at least once a week to the whole body of students attending the institution during the winter and summer sessions. This practice, in addition to the bedside teaching, was continued for half a century, when the clinical instruction in many of the older teaching hospitals was often limited to desultory conversation around the bedside in the wards. The first theatre lecture of this systematic course was delivered by Dr. James McDonnell, a very remarkable man—an intellectual giant in his day—whose name is associated with every movement for the advancement of medical education and for the relief of suffering.

James McDonnell.

If any one name is to be singled out from amongst the founders of the Belfast Medical School, as we look backwards at the present momentous stage of our progress, it must be that of McDonnell. To him we owe the origin of the first hospital established in Ireland for the treatment of fevers, and to him is due the honour of founding the Belfast Dispensary. Malcolm relates how in times of the greatest apathy towards this, his favourite, project, when almost unassisted by an encouraging hand, he continued to tend and watch over it with fostering care and unabated interest until it had reached a vigorous maturity. He was the leading spirit in the campaign that called into existence the Belfast General Hospital. As an evidence of his marvellous energy and of the manysidedness of his colossal character, it may be mentioned that he was also the founder of the Natural History Museum, still standing in College-square and still doing duty as our only scientific museum for the education in natural history of the people of the city. There stands his splendid bust in marble, alongside the mummy of an early Egyptian dynasty, and some geological specimens gathered by his own hands or chiselled out by his faithful servant, Mike, who in his day enjoyed almost as large a degree of popularity as his worthy master. In the midst of his arduous labours in the interest of humanity McDonnell found time for the pursuit of original research, and contributed valuable additions to our knowledge upon the mechanism of the circulation. His work upon the variations in the pulse under diverse physical conditions and alterations in the body posture shows the remarkable originality of a mind capable at the same time of patiently accumulating enormous numbers of observations and rightly interpreting their physiological and clinical importance. Born in the Glens of Antrim in 1762, McDonnell graduated in Edinburgh in 1784 and lived till 1845.

Though systematic courses of lectures in anatomy, physiology, and chemistry had been delivered for some years in the Academical Institution, it was not till 1835 that the Belfast Medical School, started so modestly and unpretentiously in 1820, became firmly established. In this year

(1835) chairs of surgery, midwifery, and materia medica were added to those of anatomy and physiology and chemistry, and in the following year chairs of medicine and of botany were created, all in connexion with the Belfast Academical Institution, which with the General Hospital constituted the home of the Medical School up to the establishment of the Queen's College in 1849. The first list of professors appointed to these medical chairs contained the names of men some of whom have left an indelible impression upon the science of medicine. A brief glance at their achievements will show that from the moment of its birth the Medical School of Belfast was characterised by an originality of thought, an earnest and conscientious recognition of its high mission and an intense practical trend—qualities which stand out prominently in its subsequent history, and which still remain as its chief distinguishing features after almost a century's patient and noble service.

Thomas Andrews.

The first of these men was Thomas Andrews, born in Belfast in 1813. He practised as a physician actively and successfully and was one of the clinical teachers in the General Hospital up to the year 1846. Though he finally abandoned the practice of medicine for the profession of the theoretical chemist, we justly claim him as one of those who laid the foundations of our Medical School upon a thoroughly scientific base. Bringing his great intellect to the elucidation of clinical problems at a time when purely scientific methods were not often applied at the bedside, he gave a high character to the clinical teaching at the hospital, and adapted his lectures on chemistry all through his long occupancy of the chair at Queen's College to the students of medicine in a practical manner only possible to a teacher highly trained in clinical methods. His discovery and demonstration of the continuity of the liquid and gaseous states, his achievements in the domain of the liquefaction of gases, facilitated by his discovery of the critical point in their condensation, and his research work on the latent heat of vapours, on the heat of chemical combination, and on the qualities of ozone, have gained for him an imperishable name amongst the ranks of scientific discoverers.

At this university stage in our career I feel it my duty to pay a tribute to the remarkable foresight and fearless [illegible] of this great pioneer of medical education. He was [illegible] that nothing but the [illegible] niversity could meet [illegible] never lost a suitable opportunity of impressing his conviction upon those responsible for the state of higher education in the country. In 1867 he published his "Studium Generale," in which he urged powerfully the Government of the day to elevate Owens College, Manchester, to the rank of a university of the Scottish or German type, contending that the system of affiliating teaching institutions with a central university was fatal to freedom and intellectual progress, leading to "the degradation of all high mental culture whether scientific or literary."

Henry MacCormac.

The first occupant of the Chair of Medicine, created in 1836, was Dr. Henry MacCormac, father of Sir William, the late President of the College of Surgeons of England. He was born in 1800 and lived till May, 1886. In a short sketch of the life of this remarkable man, published in the Transactions of the Ulster Medical Society, I have contrasted his mental qualities with those of Andrews. From this obituary I may be permitted to quote a few sentences. His claim to a position amongst the immortals is not that of a discoverer, of a pioneer, or of a reformer. He belongs to the rarest group of medical celebrities—MacCormac was a seer. Many of us who knew him well are only now beginning to realise his remarkable prevision. He saw clearly, as only the seer can, things whose advent, if we yet see at all, we see through a glass darkly. Andrews found out new truths after most laborious though brilliant methods of research, not advancing one step until he had patiently satisfied himself of his data; MacCormac saw them afar off by means of some gift possessed by the few, but when he paused to reason upon the nature of the truth revealed to his subtle instinct he frequently erred. Andrews's results were the outcome of the exercise of rare reasoning powers, drawing safe conclusions from observed facts, and leading with scientific precision often to important advances in knowledge.

MacCormac in all fairness must be regarded as the father and originator of the open-air treatment of phthisis and scrofula. The unity of both diseased conditions, as well as that of the so-called white swelling in joints, was clearly realised by him at an early period in his medical career. In his work entitled "The Nature, Treatment, and Prevention of Pulmonary Consumption, and Incidentally of Scrofula," published in 1855 in London, Paris, and Leipsic, he dwelt with almost painful repetition upon the influence of impure or rebreathed air as a predisposing and a vital cause of tuberculosis.

I am conscious that in an address dealing with the history of our medical school and its present position as regards medical education I am travelling outside the track of my subject in dwelling upon MacCormac's claims as the man who first put into practical shape the open-air treatment of phthisis, which is to-day regarded as one of the most important advances in modern therapeutics. I do so because it brings home to us the greatness of a mind which for many years continued to stamp its original bent upon our medical school at the most impressionable stage of its existence. It is also, unfortunately, necessary to emphasise his claims to priority, since these have been somewhat lost sight of by the prominence given to the valuable labours of Hermann Brehmer.

Two years after MacCormac had graduated and commenced the practice of his profession Brehmer was born, and when his first work appeared in Berlin in 1856, a year after MacCormac's classic was published, he was only 30 years of age, though it must be acknowledged that his researches were independent and original, since we find that he had already established a small sanatorium in Görbersdorf in 1854. Writing in 1855 MacCormac states that: "For a long period of years I have, with an increasing fulness of conviction, discerned the undesirable results flowing from an ill-renewed atmosphere. I am perhaps the only physician of my time and standing, possibly the only one who is intimately and entirely convinced that consumption is not only when taken early very often removable, but, what is of still greater importance, that with proper means and appliances it is in every single instance preventable." The proper means and appliances he defines in the constant formula to be used by the rich and poor—namely, to sleep with their windows largely open, and to spend as much time as possible in the open air. For those already tuberculous he insists that there shall be a ceaseless, unlimited supply day and night, winter and summer, of pure fresh atmosphere in the apartment of the sufferer, his rule being that the chamber atmosphere must be as pure and untainted as the open air, in which the patient should spend as much time as his strength, the weather, the season, and his means will permit. These words, which I quote from his work of 1855, may be taken as containing every vital essential of the most modern method of treating this fell disease, and he emphasises the importance of a liberal supply of highly nutritious food. It is a somewhat sad reflection that the invaluable teaching of this genius of his day required almost half a century for its full fruition. In his own time, and as early as 1855, he complained "that whilst some complied intelligently with his suggestions, others treated every direction with indifference; but to cleanse the Augean stable was a very trifle compared with the difficulties encountered by him who would unmask a single prejudice, supersede a single habit, however hurtful and pernicious to his kind." I am addressing some individuals who are old enough to remember that upon more than one occasion Dr. MacCormac figured in the local police-court, being summoned by irate patients for smashing with his walking cane the panes of glass in the windows of the sick chamber when he found these hermetically sealed against the admission of the outer air, so profound was his conviction and so consuming was the fire of his zeal.

When our great Association next honours this progressive city by its presence I feel confident that one blot upon its fair name will have disappeared—a noble statue of this great physician, I trust, shall adorn one of our leading thoroughfares, testifying to our appreciation of his genius and our gratitude for his far-reaching labours in the interest of suffering humanity. There is an excellent marble bust of this venerable sage in the art collection of the municipal library, which can supply accurate material for an ornate monument, such as has already been erected in Germany to the cherished memory of Hermann Brehmer. No more suitable time could be chosen for the launching of such a worthy project than the present, when all Ireland has been awakened by the noble crusade against tuberculosis inaugurated by Her Excellency the Countess of Aberdeen.

Alexander Gordon.

In 1847 Alexander Gordon, the originator of the radial splint and clavicular apparatus, was elected to the Chair of Surgery in the medical school, whilst its home was under the roof of the Academical Institution, and he was transferred to the new chair established in Queen's College in 1849, upon which he continued to shed an ever-increasing lustre till his retirement in 1886, an unbroken period of almost 40 years. Gordon was a robust thinker, the bent of whose powerful mind was inventive or creative, though he was also one of the closest and most accurate observers of his day—a combination of intellectual qualities not often met with in medicine. Confining his mental activity mainly to the domain of fractures, whose etiology, pathology, and treatment he found in a condition of chaos, dominated largely by empiricism, he left it with its pathological problems and clinical signs reduced to order and its treatment based upon a purely scientific foundation. If we reflect for a moment upon the state of the literature of fractures at the lower end of the radius, the outer end of the clavicle, and at the neck of the femur, when Gordon commenced his studies it might be compared to the condition of a stagnant pool, which he transformed into a clear and crystal spring. A remarkable tribute to his genius and accuracy is afforded by the revelations of the Roentgen rays when applied to the elucidation of recent fractures, a method which has corroborated in many details his views, maintained fearlessly against a host of hostile critics. In a sense, less poetical than it may seem to some of my auditors, Gordon may be said to have forestalled the use of the X rays, his colleagues being often astonished at how, guided by his highly-trained sense of touch, his vision almost seemed to pierce through the skin and soft tissues to the position of the fragments in a swollen and œdematous limb. His lasting monument will be found in his unrivalled collection of fractures, to be seen in the pathological museum at Queen's University. The influence of Gordon's teaching in the class-room, in the operating theatre, and by the bedside in the wards of the old General Hospital was a powerful factor in the advance of the medical school, nor was his power due exclusively to his originality in thought and practice; few teachers ever held a more undivided sway over the hearts of their pupils than did this fearless and honest and pure-minded surgeon.

I am addressing many of Gordon's old pupils, one of whom —our local treasurer—loves to relate a striking instance of his originality, patience, and resourcefulness in overcoming apparently insuperable difficulties. No better illustration could be given of the genius of the great surgeon who so materially assisted in the building up of our Medical School during the middle of the last century. Early in his professional career he started to build with his own hands a small sailing boat. After the final completion of his task, and not till then, did he discover that his work of art, like the famous picture of the family of the Vicar of Wakefield, was too large to be removed through the door of the apartment in which it had been created. Nothing daunted, Gordon proceeded with his own hands to cut the small vessel in two, and, after its successful removal from the loft in which he had worked at it for several months, he conceived the idea of lengthening the boat. This he successfully accomplished by the insertion of a new central portion of considerable length between the divided ends of the original, thus foreshadowing the possibility of one of the greatest feats ever performed by the modern architects of our large ocean steamers.

Peter Redfern.

From the foregoing brief sketch of a few of the many master minds which moulded the character of our local school of medicine during the critical period of its early existence, before and immediately after the establishment of the Queen's College, we are led up to the advent of the illustrious teacher whose influence more than that of any other man consolidated its varied units and created for it a reputation which placed it amongst the foremost group of teaching institutions in the United Kingdom. Professor Peter Redfern in 1860 succeeded to the Chair of Anatomy and Physiology, first established by Drummond and afterwards occupied by Hugh Carlisle. The number of medical students attending classes in Queen's College at this time, though steadily rising from its opening in 1849, had only reached the total of 116. As the fame of the anatomical department under Redfern began to travel beyond the boundaries of the north of Ireland the numbers markedly increased, so that within a period of 15 years they had doubled, and in 1881–1882 the medical roll of the College contained the name of 364 students, whilst the hospital register showed those of some other senior men pursuing their clinical studies after having completed their collegiate courses. It will probably surprise many of my auditors to hear that for several years about this period our local school of medicine was the third largest in the United Kingdom, Edinburgh and Glasgow alone exceeding it numerically. Redfern continued to fill the double Chair of Anatomy and Physiology till 1893, when he was compelled to retire owing to the operation of the age limit, the Crown having previously extended his tenure of office beyond the regulation limit in just recognition of his exceptional services. He was succeeded in the Chair of Anatomy by Professor Symington, an anatomist of world-wide fame, so that our anatomical school has enjoyed an unbroken period of nearly half a century's pre-eminence.

It is a difficult task to do justice to the many brilliant gifts of Redfern as a teacher of anatomy. The accuracy and range of his knowledge, the fascinating lucidity of his expositions, his polished oratory, and the magnetic influence which he wielded at the dissecting table and in the class-room, are still cherished memories with his many old pupils occupying honourable positions in the profession throughout the world. But if there be a single gift or quality to which we are to attribute the secret of his successful career as a teacher, or as the founder of a school of anatomists, it must not be to any of those brilliant powers just mentioned. In him the quality of *thoroughness* developed into a master passion. Every department of his anatomical work was dominated by it; with him, as regarded the teaching of anatomy and physiology, "there existed not a trifle." He might well, with pardonable pride, point to the success of his life work in the report of the inspectors appointed by the Medical Council when they stated their opinion that the students of Queen's College, Belfast, were taught a great deal too much of anatomy, for he strenuously held that an intimate and practical acquaintance with the details of anatomy must ever prove to be the only solid foundation upon which a progressive science of surgery and medicine can be erected. Into his well-earned leisure and retirement he carries with him the reverence and the love of all his old pupils. Looking back upon the strenuous labours of his long life to give to anatomy the first place, in medical education, he may justly claim to be the real founder of our new and progressive local school of operative surgery, which bears the stamp of its great sire in its thoroughness, patient and scrupulous attention to every practical detail, and in its conscientious devotion to the ideal of the sacredness of human life.

James Cuming.

During the long term of Redfern's occupancy of the Chair of Anatomy the Chair of Medicine was filled by James Cuming, who died in harness in 1899. Some of my auditors will remember him as President of the British Medical Association when your great organisation visited Belfast in 1884—a memory, indeed, which almost overwhelms him who ventures to address you to-night. Would that Cuming's mantle, along with his memory, had fallen upon his unworthy successor to this honourable position! During his tenure of office as professor he was fortunate in occupying for 34 years the office of visiting physician to the Royal Hospital, where he was the colleague of Dr. James Smith, whose powers as a clinical teacher rarely have been excelled. As Smith's brilliancy at the bedside proved a valuable asset to the Medical School, so in those days Cuming's prowess in the class-room became soon no less generally recognised. He was the thorough master of an almost perfect literary style—the outcome of a lifelong and intimate acquaintance with the best writings in ancient and modern [illegible] is class-room expositions models o[illegible]ower.

It is [illegible] of the *personnel* of any medical school in the United Kingdom has ever excelled that of our own during the "seventies" and "eighties" of the last century, when the list of our teaching staff contained such names as those of Redfern, Andrews, Gordon, Cuming, and Smith.

Recent History.

Notwithstanding, however, the brilliancy of such a galaxy, the ill-advised and disastrous legislation which effected the dissolution in 1882 of the Queen's University of Ireland, and in its stead established the examination board known as the Royal University, immediately checked [illegible] Belfast Medical School and [illegible]wth of true academic life [illegible] Dublin. The numbers of [illegible] Queen's College, Belfast, [illegible] year 1888, when the [illegible] operation, these had [illegible] responding to about 40 per cent.

When all allowances have been made for normal fluctuations, it is gratifying to find that of late years the position of our Medical School has been steadily, if slowly, improving, especially when we reckon the increasing percentage of senior students who continue to attend the clinical instruction in the hospitals after having finally completed their academical courses in the lecture halls of the College. So that we now find ourselves at the commencement of the university stage of our existence with an average roll of about 270 students of medicine preparing themselves for their serious life work at the different teaching institutions in our city.

Clinical Resources.

The mention of these institutions brings me to a most important point. I need not remind my hearers that large and prosperous art and science faculties may flourish in a university established anywhere independent of the density of the population in its immediate vicinity. It is otherwise with an efficient medical faculty, as such cannot exist unless in a centre sufficiently populous to supply every hospital facility for the practical teaching of medicine and surgery and their allied specialties. It is conceivable that hospital facilities considered adequate for the wants of a medical department attached to an affiliated college might fail to meet the requirements of the medical faculty of a university, and it behoves us as a profession to inquire into the amount and nature of the clinical pabulum placed at the [illegible] wards of 3500 beds freely available for clinical instruction in Belfast, all of which from time to time during late years have been utilised by the students attending our Medical School. These are made up in the following manner:—

General Hospitals.—Royal Victoria Hospital, 300 beds (266 of which are at present occupied), [illegible] (122 of which are [illegible] 168 beds, Union [illegible] 45 beds, Ulster [illegible] Children's Hospital, [illegible]

Eye, Ear, and Throat Hospitals.—Clifton Street Hospital, 35 beds, Great Victoria Street Hospital, 25 beds.

Skin Hospital.—Clifton Street Skin Hospital, 32 beds.

Maternity Hospitals.—Townsend Street, 32 beds, and Extern Maternity (about in all 900 cases yearly); Ulster Hospital, 2 beds (and 6 gynæcological beds), with Extern Maternity (267 cases yearly).

Samaritan Hospital.—25 beds.

District Lunatic Asylum.—1000 beds.

If we scrutinise the amount of teaching material which flows through the great extern department of the Royal Victoria Hospital annually, every case being utilised for instruction, we shall find that the number of new cases amounts to about 30,000, representing an attendance of 90,000; these, with the attendances at the externs of the Mater Infirmorum and the various special hospitals, make a huge total of about 170,000 each year. It is obvious at a glance that the clinical and extern teaching facilities in Belfast are much more than sufficient to meet the demands of a medical faculty of the largest possible dimensions. All these teaching institutions are of quite modern construction, and as the members of the Association will have the opportunity of *seeing for themselves during the week*, the Royal Victoria Hospital is probably better equipped for purposes of clinical instruction than any other teaching institution of its size in the United Kingdom. In order that you may form some idea of how this great mass of varied clinical wealth is being at present utilised, it is only necessary for me to add that outside the large staff of university professors and lecturers there are physicians and surgeons and specialists to the number of about 60 engaged actively from day to day in the teaching of medical students at the bedside and out-patient departments of the charitable institutions provided for the relief of the suffering in our city.

Laboratories.

It is unnecessary to weary you with details regarding the staff of professors and lecturers engaged in teaching at the university *in the Faculty of Medicine*, most of whom are already known to you by their valuable contributions to the literature of medicine. Nor is there any necessity to dwell upon the series of splendidly equipped new laboratories—physical, biological, chemical, pathological, physiological, and pharmaceutical—which, through the indefatigable exertions of Vice-Chancellor Hamilton and the munificence of our citizens and of the late Sir Donald Currie, have been recently added to the university buildings.

I hope I have been able to satisfy you, from the history of our past progress and from the evidences of the amplitude of our present resources, that our new university starts upon its educative mission fully equipped for maintaining the best traditions and highest ideals of British medicine. But at the present critical stage in the progress of scientific medicine and surgery there lies, beyond the venerating of ancient tradition and the living up to stereotyped, lofty ideals of teaching, a more solemn duty imposed upon the responsible heads of every medical school and faculty of medicine in each university. This duty consists in the establishment of radical reform in the curriculum, urgently necessitated by the enormous accumulations of new scientific facts and theories; and it is at once obvious that the error of clinging to obsolete ideals is less pardonable in a young university than in an ancient medical corporation.

DEFECTS OF THE MEDICAL CURRICULUM.

This brings me to the consideration of the second part of my remarks—the present unsatisfactory state of medical education—a subject bristling with difficulties; but I shall only detain you for a brief period with the most important and pressing of these difficulties. All authorities agree that a medical curriculum which was planned 40 years ago is now entirely out of date, since at that time bacteriology was scarcely dreamt of; medicine, surgery, and gynæcology were in a rudimentary state contrasted with their present condition; sanitary science was practically non-existent, and it was then still possible to obtain a degree or diploma in medicine in less than a three years' period of study. I need not remind you that the stringent regulations of the General Medical Council of to-day render it impossible for the student of medicine to obtain his qualification to practise until after the lapse of a minimum period of five medical years, or 57 months from the passing of his entrance examination and registration.

The aim of the General Medical Council in prolonging the minimum period of study from four to five years was to enable the student to devote entirely his fifth year to clinical or bedside study in medicine, surgery, and the special departments, all of which had in the meantime increased enormously in complexity and importance. But the preliminary sciences—biology, physics, chemistry, and physiology—had also grown prodigiously, with the result that the additional year has been practically swallowed up in the study of these sciences or appropriated by the specialised teachers in these subjects. (As regards the teaching of anatomy, it is obvious from the enormous development of the final or practical subjects that the prominent place justly given to this subject, whose study occupied such a large proportion of the students' time, is now no longer possible as it was in Professor Redfern's day.) The outcome of the existing regulations is that the brain of the student failing to expand in assimilative power with the growth of advancing science, we have arrived at the crux so ably propounded by Professor Starling at the Sheffield meeting last year of getting two pints into the one-pint pot. The disastrous effect of the attempt to achieve this impossibility is seen in the rather startling fact demonstrated by the investigations of the General Medical Council, which prove that the mean or average time actually spent by the medical student in obtaining his degree or diploma is not the minimum period of 57 months, but one of almost 84 months, just falling short of seven long years by only three weeks. Nor is this, in my opinion, the worst evil of the many arising out of the working of the present ill-arranged curriculum of medical education. A considerable proportion of students, after failing in passing the examinations in the preliminary subjects of physics, biology, and chemistry, or before presenting themselves to the examiners in anatomy and physiology, proceed to attend the classes in the advanced or final subjects, and put in an attendance at the hospital with the one or two sets of examinations in these earlier subjects still hanging over their heads, which paralyse their capacities for obtaining anything like an efficient training in the subjects whose practice is to become their ultimate life work.

The evil of the system which permits such a course is fully seen in the cases of those students who only succeed in passing their examination in the intermediate subjects at a stage in their career when they have completed, or almost completed, their entire academic courses and hospital attendances, with the pernicious result that their last year before qualifying is entirely devoted to the grinder or spent in cramming the undigested contents of the various text-books to the total neglect of the invaluable mine of wealth available in the wards and the extern department of the hospitals, and which they had been merely able to tap in the preceding years of their study. After more than a quarter of a century's experience as a hospital teacher and as an examiner, embracing a practical acquaintance with the working of three universities in the United Kingdom, I feel constrained to believe that in the sending out of *men qualified immediately to enter upon the routine practice of their profession*, we are, in some respects at least, behind the results obtainable in the old days of apprenticeship.

THE REFORMS NECESSARY.

It is easier to point out the evils in the existing system of medical education than to suggest remedies for them, just as it is easy to diagnose a serious malady and often impossible to suggest a remedy for its cure. But, fortunately, the indications for treatment in the case of the more important of these evils are as clear as they are imperative. The preliminary and intermediate periods, amounting to three years out of the minimum of five years, must be shortened, and the clinical period of study must be increased if we are to train more efficiently, and turn men out of our teaching institutions properly equipped for their serious life work. How is this readjustment of the curriculum to be accomplished? Obviously an enormous aid to it would be a compulsory examination in experimental physics and chemistry at matriculation. Such an examination could never dispense with the necessity of a complete academic course in these subjects; it would ensure the student having some knowledge of the principles of both sciences from the start of his college work, and enable the average lad easily to pass his further examinations in them within a period of 12 months from matriculation. Already the old notion that the stage of school life should be entirely devoted to purely literary studies is showing signs of yielding to the urgent pressure of modern ideals, which demand that boys must be trained to observe and reason upon the operations of the natural forces continually manifesting their presence in the world around them. Owing, however, to the present unsatisfactory arrangements for the teaching of science in the majority of the secondary schools, little relief is to be immediately expected from this method of shortening the curriculum of the preliminary subjects, though we can confidently count upon a steady improvement in the amount of elementary scientific knowledge possessed by medical candidates presenting themselves for matriculation; hence our new university has wisely permitted physics and chemistry to appear in the list of optional subjects for the entrance examination.

It is manifestly out of the question that we should be compelled to wait for the universal introduction of science teaching in the public schools before attempting to shorten the curriculum in the preliminary medical subjects. Moreover, such a consummation, however devoutly wished for, could not be expected to aid us effectually in dealing with the still more important studies of physiology and anatomy. There is a growing conviction, amounting amongst those best qualified to judge aright in this matter to a consensus of opinion, that a prolongation of the period devoted to clinical studies can only be achieved (without unduly lengthening the entire curriculum) by *a radical change in the method of teaching the entire group of preliminary and scientific subjects.*

The crux of the question centres itself in the problem of instituting the desired reform without lowering the standard of the student's knowledge in these subjects. It would be a retrograde, and perhaps disastrous, epoch in medical education should each of our specialised teachers begin to realise that his own particular subject was not the most important one in the curriculum; but "Art is long and Time is fleeting," and, as Sir Felix Semon reminds us, "Technique is difficult." Were I placing merely my own convictions—the outcome of years of thought and observation—before you upon the urgent necessity of reform in the teaching of physics, biology, chemistry, physiology, and anatomy *to the medical student*, I would be overwhelmed by the feeling that I was treading upon dangerous ground, beset with many snares and numerous pitfalls; but the University of London has boldly declared for reform, and has decided that the teaching of these subjects must be conducted *with due regard to their bearing upon the special requirements of the student of medicine.* A fact which ensures the success of this great revolution is the pleasing one that the campaign is being led by the teachers of these sciences.

Professor Starling, a member of the Senate of the University of London, who occupies the Jodrell Chair of Physiology in University College, made the spirit of the new regulations clear at our last annual meeting in Sheffield. He said we must acknowledge that the present training in science received by the medical student fails in its end and does not make him scientific. The words of this great teacher of one of the intermediate subjects are so weighty they will bear repetition when he states "that from the very commencement of his medical curriculum the work of the student should be directed; every scientific subject which he studies, whether it be chemistry, physics, or physiology, should be considered only in its bearings on his future work as a medical man." I would venture to suggest that these words should be written in letters of gold and set up in the retiring-room of each teacher of the preliminary and intermediate subjects in our universities and medical schools, when soon we would cease to see the lamentable fiasco of the attempt to make every medical student an accomplished physicist, an analytical chemist, an experimental physiologist, a practical botanist, and an expert zoologist, as these phantoms dangle before his mental vision whilst he is already far advanced in putting in a vain and perfunctory attendance at his final classes, or whilst he is absent-mindedly sauntering about the extern department or wandering aimlessly through the hospital corridors. Professor Starling maintains that this "directed" method of teaching should also be applied to the subject of anatomy, where the minute knowledge which is insisted upon at the present time as regards the direction of muscular fibres, the insignificant markings on the bones, or the identification of fragments of human bones can have no bearing on the student's future work, even if he is to be an operating surgeon, and that all anatomy should be learned as surgical and medical anatomy. He believes that "by such a method, far from sacrificing the scientific training of the student, we would ensure that the whole of his science studies, preliminary or intermediate, would be built up with his clinical training into one compact scientific fabric—the science of man and his diseases."

The application of the principle of this applied or directed method of teaching is planned by the Senate of the University of London to reduce the former three years of preliminary and intermediate study to two years and a half, and the new arrangements even permit of this period, under certain conditions, being further reduced to two years. It is to be noted, however, that as the clinical part of the student's course is now to be fixed at three years there is, therefore, a lengthening of the entire curriculum from the minimum of five to five and a half years. Since, however, only a small percentage of students are able to graduate under about six years, it is confidently anticipated that by the better division of work the new arrangements will really shorten the entire period of study. These new regulations have come into operation in the London University during the present month.

Beyond all shadow of doubt, the time has fully come when a general and complete overhaul of the medical curriculum in all the universities and in every medical school in the United Kingdom is urgently necessary. There can also be little doubt that the reconstruction must be carried out upon the lines laid down by the University of London.

THE ATTITUDE OF THE QUEEN'S UNIVERSITY OF BELFAST.

The 20,000 members of the great British Medical Association have a right to ask what is the attitude of the Senate of the new Queen's University of Belfast regarding the programme of medical education. This is not a question whose interest is exclusively centred in the functions of the General Medical Council, since the honour, the efficiency, and the traditions of the profession are more or less influenced by the accession of each batch of medical graduates permitted to swell its ranks every spring and autumn through the new portal. Nor is it a subject of interest only to the members of the profession resident in Ireland, since a considerable proportion of our medical graduates, as in the past, will ultimately seek England, the public services, and our colonies as the spheres of their future life-work.

I rejoice at being in a position to give an answer to this question which can hardly fail to prove satisfactory. We have modelled our regulations regarding the medical curriculum upon lines somewhat similar to those inaugurated by the University of London, and being an entirely new university, absolutely untrammelled by any vested teaching interests, I respectfully but confidently submit that we have been able in some ways to improve upon the new regulations laid down by that august institution without, we believe, any lowering of the recognised standards of excellence. If we have been delayed till now in the realisation of our aspirations towards achieving university rank, the delay has enabled us from the start of our career to seize on the latest improvements and most advanced developments in medical education, which in recent years have been grafted upon the various and varied curricula of the older universities and long-established corporations in their attempts at keeping pace with the ever-swelling tide of medical knowledge. In the planning of our new curriculum we were most fortunate in having the aid of the supervision of one of the Commissioners of the University in Sir Donald MacAlister, the able President of the General Medical Council, in whose unique personality is combined the rarest business acumen with the most profound knowledge of the requirements of progressive medical education.

Though not presuming to state that my distinguished colleagues who teach the preliminary and intermediate subjects in the Queen's University of Belfast all go so far as to endorse in its entirety every view of the eminent professor in University College whom I have already quoted, I am justified in stating that they have always conscientiously and successfully aimed at directing the studies of the medical student from the point of view of his future serious vocation as far as our intimate connexion with the cumbrous and somewhat obsolete machinery of the now expiring Royal University permitted.

I shall not risk wearying you with minute details of the curriculum of our new university; suffice it to say that within a period of one year, consisting of one winter and one summer session, from matriculation the student can present himself for examination in all the preliminary subjects—experimental physics, chemistry (both theoretical and practical), and botany with zoology (both theoretical and practical). Within 12 months more he can complete his curriculum and examinations in anatomy and physiology, so that, if diligent and of average ability, he finds himself, before entering upon his third winter, completely free from study and from attendance upon all the classes of the preliminary and intermediate subjects, and privileged to give henceforth his undivided attention for a period of three whole years to practical clinical work and attendance upon the lectures devoted to the final subjects, whose practice is to constitute his life-work. By this judicious arrangement of his time and study the new university has thus been enabled to change the usual three years devoted to preliminary education, and the two years into which the clinical study had been squeezed, into two years of preliminary training and three whole years of clinical work. That this result is not obtained by sacrificing any of the time formerly devoted to the teaching of these scientific subjects is evident upon glancing at the calendar, which shows that during the first two years the student is compelled to attend no fewer than 16 separate courses of lectures, each course being of the usual length and consisting of the recognised number of lectures. The standard of excellence is maintained by arranging that the examination in each subject shall be conducted at the termination of each session, that the instruction given shall be in every possible way carried out on practical or experimental lines laid down upon the directed method already mentioned, in which the bearing of principles and facts are presented with due regard to the wants of the student and of the future practitioner of medicine. Whilst there is thus no danger of any lowering of the standard of scientific knowledge required of the student, ample provision is made for the maintenance of his clinical training at a high level by compelling him to avail himself for a minimum period of three years of the almost unrivalled hospital facilities at the command of the new university.

The spirit of thoroughness in which our curriculum has been conceived is further demonstrated by a regulation which prohibits the student's attendance upon lectures on the final subjects until he has passed his examinations in the preliminary subjects.

In conclusion, I trust that this necessarily fragmentary sketch of the origin, development, and progress of the Belfast Medical School under the master minds of its early teachers, whose present successors are determined to uphold its traditions and keep abreast of the tide of advancing knowledge, will carry the conviction to the minds of my auditors that a great and free university has arisen to shower its blessings upon our province, to carry the lamp of learning, and to bear upon its wings the balm of healing to the remotest parts of our colossal empire.

Address in Medicine

ON

PROGRESSIVE MEDICINE AND THE OUTLOOK ON TUBERCULOSIS.

Delivered at the Seventy-seventh Annual Meeting of the British Medical Association

BY R. W. PHILIP, M.A., M.D. EDIN., F.R.C.P. EDIN., F.R.S.E.,

PHYSICIAN AND LECTURER ON CLINICAL MEDICINE, ROYAL INFIRMARY, EDINBURGH; AND PHYSICIAN TO THE ROYAL VICTORIA HOSPITAL FOR CONSUMPTION, EDINBURGH.

MR. PRESIDENT AND GENTLEMEN,—It is fitting that the first word this afternoon should be one expressive of my sincere thanks to the Council for the invitation with which they have honoured me [illegible] the annual meeting of the [illegible] request I am sensible of [illegible] compliment, which is implied. As years go by the choice of a subject does not grow easier. The immensity of the field constitutes an increasing difficulty.

Turning the matter over soon after the invitation reached me, I chanced to pass my old school, left, almost to a day, 35 years ago. It occurred to me that, in place of attempting to project a bird's-eye view of medicine as a whole, it would be well to limit attention to one department which illustrates in striking fashion the extraordinary revolution of [illegible] in little more than a generation. [illegible] of modern medicine on [illegible] the choice. No subject in medicine has wider interest. No assembly can appraise, as this great Association can, its significance and magnitude. You know its difficulties and have to face them every day. I am influenced, too, by the fact that the Association meets this year in Ireland, where, thanks to the admirable energy of Her Excellency the Vice Reine and the generous coöperation of the medical profession, a great antituberculosis movement is in progress. Nor can I forget the striking part played by the city of Belfast in times gone by through the remarkable labours and writings of Dr. Henry MacCormac, and in more recent times by those who are yet with us.

RETROSPECTIVE.

To give greater precision, let me divide the 35 years into five lesser periods of seven years each. The first period (1875-81) was one of darkness and fog. The great work of Laennec and Louis was threatened with eclipse. The unity and specificity of the tuberculous process were obscured. Terminology was vague and inexact. Tuberculosis of the lung was labelled catarrhal pneumonia, with three stages of congestion, consolidation, and excavation. A "neglected cold" played a chief causal rôle. The hopelessness of therapeutics was depressing. Here and there appeared glimmering of light. Experimental research on the earlier lines of Villemin presaged the dawn.

The commencement of the second period (1882-88) saw the advent of daylight. Koch's announcement to the Physiologische Gesellschaft of Berlin, on March 24th, 1882, came like sunrise to a sleeping city. The discovery of the tubercle bacillus inaugurated a time of Sturm und Drang—the strife of critics and opposing doctrines. The tremendous significance of the brilliant discovery could not be realised at once. Time was needed for the correction and adjustment of older views. Research had to develop on fresh lines. The character, life-history, properties, and morbific activity of the tubercle bacillus were studied by a host of observers. The conception came gradually—not an absolutely new conception indeed—that tuberculosis, notably pulmonary tuberculosis, must be given a place among infective diseases. The old feeling after truth, which led the Italian and Spaniard almost a century before to pass enactments prescribing preventive measures against tuberculosis, was found to rest on scientific fact. Gradually there emerged indications of a larger outlook towards prevention.

During the third period (1889-95) observation and research were pursued with increasing exactness and better result. The period is remarkable because of two events: (1) the announcement of tuberculin; and (2) the more general adoption of the doctrine of aerotherapy, a doctrine promulgated long ago, but little apprehended or applied. The intimation by Koch in 1890 that he had obtained in tuberculin an agent of specific value in the diagnosis and treatment of tuberculosis was an event only second in importance to the announcement of the bacillus itself. It needed years, however, to enforce the conviction that tuberculin, which was received with mingled criticism and almost hooted from the stage, embodied a principle of the greatest significance to medicine.

The fourth period (1896-1902) saw the more rapid spread of antituberculosis activity throughout the civilised world—the increasing determination of scientific, social, and, to some extent, official effort towards the tuberculosis problem. While experimental research was pursued with keenness, men's minds were awakened to the large issues of preventive medicine. This was the time of more general development of the sanatorium. The tuberculosis dispensary, inaugurated in the "eighties" as a centre of antituberculosis operations, aroused attention. Notification was admitted as a practical measure. Tuberculosis associations were founded in different centres. Conferences and congresses began to be held. The commencement of the twentieth century found the subject pretty much in the air.

The fifth and last period of seven years (1903-09) is remarkable for the development of larger views on immunisation and the appearance of the opsonic doctrine and its application to therapeusis as a means of directing vaccine-therapy. Diagnosis has been made more exact by various adaptations of tuberculin. This is also the period of more rapid evolution of preventive measures. The physician and the sanitarian have joined hands, and have been aided not a little by thoughtful social workers who recognise the vast part played by tuberculosis as an agent of national devitalisation and impoverishment. The nations of the world are falling into line. Repeated international congresses have borne excellent fruit. With exchange of ideas endeavour has become better directed and more uniform. The significance of organisation and coördination of effort is gradually being appreciated. Administrative control is taking practical shape. And so the great work goes on.

PRESENT POSITION AND OUTLOOK.

To-day I invite you to pause for a brief hour and think what the discovery of the tubercle bacillus has meant to medicine and to the world, and what it may mean. Nor deem this a trite or exhausted subject. I hope to succeed in showing that, great as have been the advances already made, still greater are the possibilities which the discovery implies. Consider the matter more closely. The determination of the essential cause has called order out of chaos. It has thrown to the winds the vague, nebulous talk of dualism which long perplexed medical science. Tuberculosis, however various its aspects, is one indivisible entity, dependent essentially on the presence and activity of one organism. Behind the changing pathological and clinical appearances the tubercle bacillus remains single and constant.

[Here Dr. Philip criticised the usually adopted nomenclature and classification of tuberculosis as being too anatomical, and not taking into account systemic manifestations, and continued :]

DIAGNOSIS AND PROGNOSIS.

The discovery of the tubercle bacillus in the patient's expectoration affords bacteriogical proof of tuberculosis. This is incontestable evidence. It is the evidence which we seek for in dead tissues. But from the physician's point of view much more is needed. In the first place, if he wait for the appearance of the tubercle bacillus in the discharge he waits too long. The occurrence of the bacillus in the expectoration signifies a tuberculous invasion which has made considerable advance. The disease has progressed far before it takes the form of a discharging lesion. The physician's duty is to conclude the diagnosis prior to this. Further, the detection of the bacillus in the discharge, or the determination, by one or other of the more recent bacteriological tests, that the patient is tuberculous, yields but a partial diagnosis from the standpoint of prognosis. Unfortunately the present tendency is to say, on the one hand: Given no tubercle bacillus in the discharge, we may not diagnose the condition as tuberculosis; and, again: Given the bacillus in the discharge, the diagnosis is one of tuberculosis, and there's an end of it. But *quâ* prognosis, much more is needed.

In respect of early diagnosis and the completer diagnosis on which are based both prognosis and treatment, the physician has methods of determination beyond those of the laboratory, which can be refined and perfected only by careful, patient, and prolonged study at the bedside. The physician, while making use of all bacteriological advances as aids to diagnosis, cannot afford to forget that there is evidence imprinted on the patient's every tissue and organ which, when read by the seeing eye and interpreted by the trained senses, gives completeness of view otherwise unattainable. The physician is primarily the thoughtful observer of Nature. Familiar with the features of healthy activity as these manifest themselves in every organ, he becomes quick, by repeated observation of disease, to catch the first slight deviations which indicate that the physiological has become the pathological. In illustration, let me cite a simple case.

Some years ago I was asked to see a young lady suffering from pulmonary tuberculosis, who was extremely ill, indeed almost moribund. There was little to be done. In passing downstairs from the sick room I happened to meet a bright girl with whom I exchanged a few words. After expressing an unfavourable opinion regarding the patient, I ventured to ask who the girl was whom I had met on the staircase. To the reply that it was the patient's younger sister, I suggested we should direct treatment to her. The immediate rejoinder was: "But there is nothing wrong with her." I heard no more of her for 20 months, when I was asked to see her on account of pulmonary tuberculosis. The doctor in attendance reminded me of the previous incident and indicated that the girl had "kept well" till a fortnight ago, when [illegible] of expectoration sent to the laborat[illegible] tubercle bacilli. Examination of the [illegible] ·eral disease and pronounced systemic [illegible] moment to the patient had slipped by during which the disease was slowly making way. It was only when the lesion came to be a discharging one that the suggested diagnosis of 20 months before was seriously considered. In spite of speedy adoption of treatment, and a brave fight on the part of the patient, she died. Had treatment been instituted at the earlier date the unfortunate issue would probably not have occurred. Such incidents are of frequent occurrence.

The extent to which faith is limited to the bacillary diagnosis is serious. I have before me a letter from a bacteriologist who, at the request of a throat specialist, had received a specimen of sputum from a patient in whom, to my knowledge, the diagnosis of pulmonary tuberculosis had been made six years ago, and who had done remarkably well. The writer reports that he found the patient discharging "a very large number of tubercle bacilli, which indicated that it was an advanced and progressive case of phthisis but still not hopeless." It is clear that neither the unfavourable verdict nor the subsequent reassurance, coming from one who had never seen the patient, can be admitted as of much value. What I am anxious to urge is, on the one hand, that the bacteriological diagnosis comes frequently too late, and in any case should not be waited for without an estimate of the results of every other method of examination, and, on the other hand, that the bacteriological diagnosis is much too narrow an issue on which to base prognosis in a given case. While, broadly speaking, the presence of a large number of tubercle bacilli in the discharge points to a considerable focus of disease, the actual number *per se* is not a sufficient gauge of the stage or gravity of the case. To the trained clinical eye there are a score of other points which must be appraised in order that the diagnosis may be of prognostic value.

TUBERCULIN IN DIAGNOSIS.

The subcutaneous injection of tuberculin, as first proposed by Koch, is occasionally of much value. There occur every now and again in the experience of the best clinician cases where the symptoms, physical signs, and clinical course are difficult of interpretation—cases where the possible presence of tuberculous disease means too much to the patient to justify doubt or delay. In such instances the use of tuberculin is clearly indicated. Resting on an opinion formed by a persistent use of the method since its first introduction, I can testify to its value and its freedom from risk. There are also available more recent adaptations of tuberculin diagnosis, which include the cutaneous, percutaneous, and ophthalmic tests. These have a wide range of application. Perhaps the most generally serviceable is the cutaneous. The percutaneous is a simple modification of this, in which the skin remains unbroken. The ophthalmic or conjunctival has similar application where there is no contra-indication because of existing eye disease.

These methods, which are readily carried out, yield convincing evidence as to the presence or absence of tuberculosis in the given *individual*. They do not, of course, afford certain proof—although the presumption may be present—that the *particular symptoms or lesion* under consideration are of tuberculous origin. They justify the diagnosis that the individual has tuberculosis, while they leave the localisation of the lesion to other means. In this sense the cutaneous and ophthalmic tests are commonly less conclusive than the subcutaneous. On the other hand, the former are often preferable. Thus they may be preferred when the point to be determined is the general one, Is the patient tuberculous? They may be preferred—especially the cutaneous—when the hypodermic method might be objected to either by the patient or his friends or when the character of the lesion makes subcutaneous injection undesirable. The external methods—and in most cases the cutaneous—are preferable when an extensive test involving many individuals is undertaken, as in a public institution, for the purpose of determining the amount of tuberculosis present. In respect of all these tests it is unfortunate that, while they commonly indicate with remarkable certainty the existence of a tuberculous lesion, they fail to discriminate, so far as present methods go, between lesions of comparatively old and quiescent character and commencing lesions of aggressive nature. They fail also to detect some of the worst cases, notably disease rapidly advancing towards a fatal termination.

ETIOLOGICAL RELATIONSHIPS OF CHILDHOOD.

From the larger point of view we are much indebted to tuberculin for convincing evidence of the vast frequency of tuberculosis. Of paramount importance is the conclusive testimony it bears as to the frequent occurrence of tuberculosis in children. Its use has confirmed in remarkable fashion estimates, concluded on other clinical grounds, which have sometimes been criticised as excessive. Thus conclusions published by me, which showed that of groups of school children from 6 to 14 years of age no fewer than 30 per cent. presented stigmata of tuberculosis, have been thought extreme. Yet observations by means of the cutaneous test go to show that such conclusions are within the mark. Much evid[illegible] the point. In the absence of [illegible] scale from London or other great [illegible] continental observations. Statistics from the city of Vienna are available which deal with large numbers of children. They include (A) cases examined post mortem, and (B) cases tested with tuberculin. The figures are as follows:—

[illegible] were found to be [illegible]

Group I.	(1st year of life)	showed	15	per cent.	tuberculous
,, II.	(2nd ,,)	,,	40	,,	,,
,, III.	(3rd to 4th year)	,,	60	,,	,,
,, IV.	(5th to 6th year)	,,	56	,,	,,
,, V.	(7th to 10th year)	,,	63	,,	,,
,, VI.	(11th to 14th year)	,,	70	,,	,,

(B) Tuberculin results:

(*a*) Of 988 consecutive patients coming to hospital and tested by cutaneous method (von Pirquet).

Group I.	(as above)	showed	16	per cent.	positive.
,, II.	,,	,,	24	,,	,,
,, III.	,,	,,	37	,,	,,
,, IV	,,	,,	37	,,	,,
,, V.	,,	,,	57	,,	,,
,, VI.	,,	,,	68	,,	,,

(*b*) Of 509 consecutive patients in hospital for diphtheria, scarlet fever, and other acute infections (except measles), tested cutaneously, and in case of doubt subcutaneously (Monti and Hamburger), 271 were positive, that is, circa 50 per cent. Or, taking them in groups.

Of Group I.	(as above)	undetermined.		
,, II.	,,	9	per cent.	were positive.
,, III.	,,	27	,,	,,
,, IV.	,,	51	,,	,,
,, V.	,,	71	,,	,,
,, VI.	,,	94	,,	,,

It is to be kept in view that the figures quoted are based on investigations among children of the poorer classes, and refer to tuberculous *infection* and not to clinically determinable *illness* merely. For the present we are concerned with the actual *distribution of tuberculosis* throughout large communities. It is also to be understood that the conditions pertaining in Vienna and correspondingly the incidence of tuberculosis are not strictly comparable with those in our own large towns.

None the less, collective evidence from many sources emphasises the view that it is especially in childhood that the tuberculous seed is sown. Tuberculosis is an all-pervading blight. Its occurrence would seem traceable largely to the nursery, or at least to the period of childhood. The German saying, "Am Ende hat Jedermann ein bischen Tuberkulose," might in the light of modern observation almost read, "Tuberculosis is commonly contracted in childhood." The significance of this can hardly be exaggerated. The frequency of tuberculous infection in childhood explains much which previously gave rise to endless speculation. If we modify slightly the doctrine of heredity which formerly held sway and ally it with that of the survival of the fittest, we shall come near to the truth. Heredity means not transmission of the disease, but of tissues which are extra liable and extra vulnerable. The widespread distribution of the disease and unhealthy environment mean the probability of infection in less or greater degree. The more liable tissue becomes more certainly infected, and the more vulnerable tissue suffers in greater degree. The less liable may escape altogether, and the less vulnerable resist successfully.

If the conclusion which seems forced on us be correct, that in a majority of instances infection occurs in childhood, we are faced with a problem of totally different complexion and proportions from that which was previously conceived. To solve it we must search for causal conditions in the life of the child. It is impossible on the present occasion to condescend on details as to channels of infection. Suffice it to say that prolonged observation has led me to conclude that inoculation may occur by way of the mucous passages at any point from the mouth and nostril downwards. I believe this is especially frequent in the naso-pharyngeal, tonsillar, and faucial regions From the point of entrance there is usually a slow dissemination by way of the lymphatic circulation. The factors essential to invasion are devitalisation of the tissues and the presence of the bacillus.

In answer to the query, Where does the bacillus come from? it is natural and tempting to trace infection in childhood chiefly to infected milk-supply. But do the facts bear this out? Tuberculin tests show that tuberculosis is relatively less common during the first two years—when, if milk were the chief agent, we might expect it to be greater —and evidence of infection becomes progressively common as age advances. The facts of comparative ethnology tend also to qualify the view. For tuberculosis flourishes abundantly in not a few countries where feeding with milk from cows or other animals appears unknown. I am assured by numerous competent observers abroad that tuberculosis abounds in districts where the use of milk for alimentation is unknown. The extent to which tuberculosis depends on the ingestion of bacillus-containing milk remains, therefore, a moot point. It seems rather as if some other cause were operative—a cause common to home and school life. The incidence of pulmonary tuberculosis shows a steady increase as the child grows. The ratio of increase is greater about the time the child goes to school. One morbid influence seems constant throughout the progressive stages of the child's life—namely, the comparative withdrawal of the developing organism from the natural and healthful stimulus of the open air. The facts appear to point conclusively to the relatively airless conditions of home and school life as a chief etiological factor. This view is corroborated by observations made under the system of domiciliary visitation which forms a leading feature in the activity of the Victoria Dispensary for Consumption. Under the system the home of every patient coming to the dispensary is systematically inspected by nurse and doctor. In addition to inspecting the house the doctor holds a "march past" of the household, so that other cases of infection may be detected as early as possible. The frequency with which several members of a household—it may be half a dozen children—are found to be concurrently affected is striking. There is a remarkable coincidence between the airlessness of the house and the frequency of disease. Sometimes every member of the family presents stigmata of the disease. Such homes are veritable "nests" of tuberculosis.

In this connexion I venture the suggestion that it is to the extensive distribution of tuberculosis in childhood that we must trace the frequency of the graver symptoms and complications which occur in such infections as measles and whooping-cough. The more carefully we have regard to complete diagnosis, the more frequently will it be found that tuberculosis lurks behind the more acute illness. It is often stated that pulmonary tuberculosis occurs as a *sequela* of measles and other infections. Are there not grounds rather for believing that such infections tend to assume the graver character because of *pre-existing* tuberculosis? Do not such infections frequently arouse into activity a pre-existing tuberculosis? Tuberculosis is, I believe, to be credited with a much greater proportion of mortality in childhood than is usually conceived, and is largely responsible for the aggravated manifestations of otherwise simple ailments.

TUBERCULOSIS IN COMMUNITIES.

Turning to the occurrence of tuberculosis in the community generally, I may recall calculations made a number of years ago as to the ratio between mortality and incidence of pulmonary tuberculosis. These led me to the conclusion that the mortality within a district might safely be multiplied by ten to express the number of cases of pulmonary tuberculosis worthy of medical surveillance, and I suggested that this number might be further increased without exaggeration. Subsequent observations have confirmed the belief that the estimate, far from being excessive, errs probably on the low side. The results obtained by means of the newer methods of diagnosis are strongly corroborative. If we reckon not merely patients who are so evidently ill as to require medical supervision, but the entire number of persons who give a positive reaction to tuberculin, the sum total is vastly greater. Such facts have a very practical bearing on prevention and treatment. They testify to the tremendous grip which tuberculosis has obtained on the race and its immense ramifications throughout the social organisation. They emphasise the significance of measures directed to the better sanitation of dwellings and schools as well as workshops, offices, &c. They illuminate and illustrate the housing question—using the phrase in the widest sense—as nothing else could do. No less do they accentuate the great need which exists for an organised and coördinated plan of operations in relation to tuberculosis as it occurs in our social communities. With so great a mass of tuberculous material to handle we cannot afford merely to wait and treat individual patients as they happen to present themselves at out-patient departments. We must search for them in their hiding-places. We must track them to their breeding-grounds.

Towards this end *concerted action* is desirable. We must obtain all available information as to the distribution and spread of the disease with a view to its prevention and eradication. This is the justification of notification. Much more is needed. Approaching the matter from the standpoint of the pathologist, I was led some 22 years ago to propose the establishment of the Consumption Dispensary as a central institution which should concern itself with every aspect of the tuberculosis problem, and would have regard especially to the patient's home conditions in relation to his own treatment and the limitation of the spread of the disease throughout the household. By the continuous activities of the tuberculosis dispensary and the system of domiciliary visitation to which I have alluded, there is maintained a ceaseless campaign and successful raid on the disease. If properly worked, there will be accumulated a remarkable mass of information regarding tuberculosis in the given district. Thus, in Edinburgh, the activities of the Consumption Dispensary have tended to the completion of a satisfactory plan of antituberculosis operations, which includes compulsory notification, a sanatorium for early cases with approximately 100 beds, a working colony, a hospital for advanced and dying cases with 62 beds, in addition to suitable and extensive accommodation for patients of the pauper class under the Poor-law authorities. The several factors in the scheme are on terms of intimate relationship and coöperation. The scheme is closely related to the municipality through the medical officer of health, and by many links to the Charity Organisation Society and other such agencies. As illustration of the significance to the community of such concerted action, it is noteworthy that while during the first ten years of the development of the scheme, when its activities were more restricted, the mortality from pulmonary tuberculosis in Edinburgh fell 12·8 per cent., in the succeeding ten years (1897–1906) the mortality further fell to the extent of 42·1 per cent. Without tracing this remarkable drop entirely to the activities of the system it seems fair to interpret these as chiefly contributory to the result.

The further goal towards which all effort is directed is the recognition by the State and the various administrative bodies concerned that tuberculosis is a social evil, the existence and effects of which call for consideration and active interference. The change which has come over the official attitude of the country is eminently satisfactory. So far as England is concerned, the most significant indication is found in the fact that last year there was issued by the Local Government Board an order calling for the notification of all cases of pulmonary tuberculosis occurring in patients under the Poor-law. In Scotland an advanced position was taken some years ago In a Memorandum dated March 10th, 1906, pulmonary phthisis was declared by the Local Government Board of that country to be an infective disease within the meaning of the Public Health Act and the various elements in what may be described as the Edinburgh scheme were recommended as collectively forming the basis of a national scheme of antituberculosis measures. Ireland, thanks largely to the attitude adopted by her Local Government Board, is in possession of a Tuberculosis Prevention Act, which became effective on the first of the present month, and which gives her potentially the entire machinery for a complete and effectual campaign. These are striking indications of ripening opinion. Taken along with the wider public health enactments which have been a conspicuous feature of recent legislation, they afford a gratifying promise for the future.

THERAPEUTICS

Let me invite you to consider briefly two aspects of treatment. The first of these has no direct relationship with the tubercle bacillus—namely, aerotherapy. The second depends essentially on the bacillus—is, indeed, the outcome of our growing acquaintance with that and other organisms. I refer to tuberculin and vaccine-therapy.

The Great Principle of Aerotherapy.

Although, as the cynic may remind me, the great principle of aerotherapy dates from the Garden of Eden, somehow as time went on the principle ceased to be followed save by a few. The experience of the past two decades has greatly influenced the medical attitude towards aerotherapy. Its methods have gained an assured place in therapeutics. We have come to recognise from a comparative study of pulmonary tuberculosis as it occurs throughout the world that *it is not a disease of any one latitude or* climate. The fallacy which in the popular, and perhaps also in the medical, mind associated consumption particularly with these islands has been exposed. The relative infrequency of consumption in England and Scotland as contrasted with other European countries has not only contributed to dissipate ignorance as to its etiology, but tended actually to a reversal of the conception that climatic conditions have to do with its production. The pioneer work of the earlier sanatoriums in this country led rapidly and certainly to the conclusion that open-air treatment was a method of universal application. Facts and statistics have speedily accumulated which go to show that tuberculosis results chiefly from the exclusion or insufficient supply of fresh air in the dwelling-room, workroom, and other haunts of man, and, further, that in proportion as the supply of air and sunlight is improved, under better conditions of sanitation, there follows a corresponding reduction in the mortality from tuberculosis. Not only this, but there is abundant evidence that open-air treatment is successful in proportion as it is carried out completely, in winter no less than in summer. Indeed, there is not wanting support for the belief that the results obtained under open-air treatment are fully better during the colder than the warmer months of the year. Nor is it too much to contend that the application of aerotherapy has completely changed the clinical features of pulmonary tuberculosis. Under proper aerotherapeutic conditions the classic type of disease, as described from generation to generation in the past, has ceased to be The aspect of the patient is metamorphosed. The delicate pink-and-white colouring or the hectic blush usually described is frequently replaced by a ruddy look. *Pyrexia disappears* marvellously. Within a short time temperatures which have been swinging for weeks tend to become normal. The rapid pulse is slowed and blood pressure increased. Night sweating is practically unknown. Cough quickly lessens or disappears and expectoration is correspondingly reduced. Appetite picks up and digestive disabilities disappear. Lassitude and disinclination for effort, physical and mental, pass away, and the patient becomes once more keen and fit for [illegible] His entire physiology returns [illegible] tion of the consu[illegible] treatment on aerotherapeutic lines, sounds exaggerated and false. The brilliant results achieved under aerotherapy in the arrest of what seemed hopeless conditions of disease afford encouragement for the wider adoption of open-air measures with a view to prevention. It is remarkable how far prevention lags behind treatment. What is capable of effecting the cure of definite tuberculosis is *a fortiori* capable of preventi[illegible] this in theory, but the [illegible] hearted and faltering. This [illegible] we have a constant object-lesson in the relatively low place which England and Scotland occupy in relation to tuberculosis mortality as compared with other nations. There *is little doubt that this finds its explanation in chief* part in the habits of our people, their love of outdoor sports and the like, and in the continuous and steady amelioration of housing conditions from successive enactments which have been passed during three-quarters of a century. The history of medicine abundantly shows that where therapeutic procedure is based on physiology the methods of application are simple and direct. This is conspicuously true of aerotherapy. The accumulated experience of recent years has established three general propositions of much significance.

1 Aerotherapy is a measure of universal applicability in all lands. There is no climate specially favourable for its practice. The advantage of brighter, warmer climates lies chiefly in the greater *facility* and comfort with which *it may* be carried out Open-air treatment seems more natural when the sun is shining. On the other hand, in warmer climates there are inherent difficulties to the carrying out of the system all the year round. It may be doubted whether any climate, taken as a whole, is more suitable for the purpose than that of the United Kingdom.

2. Aerotherapy is of universal applicability in every sick room. It is not a special system to be practised in special institutions. It is utilisable in the bedroom of the ordinary dwelling as certainly as it is in the ward of a special hospital. Although more conveniently carried out *in the sanatorium, it may be used no less completely* and effectively in the ordinary dwelling house if only the principle of application be rightly apprehended. There is no need to send patients to sanatoriums *merely* on this account. Sanatoriums have their uses. They are serviceable, especially in the interest of patients who, for one reason or another, *cannot have a proper régime maintained in their own home.* But even the poorest—and still more easily the well-off patient—can enjoy the advantages of aerotherapy at home. This is a significent admission because it carries with it the further important conclusion that a sanatorium does not require, in order to be effective, to be erected in an inaccessible place, removed, it may be, a hundred miles from the centre of population which it especially serves. Many mistakes have been made in regard to this in the past. Much unnecessary expenditure and inconvenience have been caused. If a sanatorium is established for the poorer classes of a town it is eminently desirable that, while it should be removed to a sufficient distance to protect it from smoke and dust, it should still be sufficiently under the eye of the citizens to constitute from day to day an object-lesson in the application of aerotherapy.

3 Aerotherapy, while especially indicated in tuberculosis, is a measure of widest applicability in relation to disease. It is a mighty principle of treatment both from the curative and from the preventive point of view. I have already alluded to the remarkable change in type which occurs in pulmonary tuberculosis when treated on open-air principles. No less striking is the absence of complications as compared with their frequency under the protective method Throughout 15 years of constant experience of aerotherapy in the *Royal Victoria Hospital for Consumption I have watched* closely for the occurrence of pneumonia, or pleurisy, or bronchitis, and have failed to meet them. Their absence from a considerable community, all of whom have already weakened lungs, is singular [illegible] there has never been an outb[illegible] it is the rarest occurrence to [illegible] duty even for a day. It would seem, indeed, that the application of aerotherapy is without limits, provided reasonable care be taken to preserve the warmth of the body. We are only awakening to the full significance of this great cleansing, antidotal, and vitalising principle whose applicability in medicine is no less far-reaching than that of *asepsis in surgery. It was a far-seeing, clear-visioned poet* who wrote—

> "Air, air, fresh life blood, thin and searching air,
> The clear, dear breath of God that loveth us.
> * * * *
> Water is beautiful, but not like air."

The progress of surgery within *recent times is sometimes* contrasted with that of medicine to the disadvantage of the latter. It is worthy of note that the remarkable developments of modern surgery are the result of the application of one or two great principles which may be described as medical rather than surgical. The two principles which have revolutionised surgery—namely, anæsthesia and asepsis—have allowed the surgeon to proceed fearlessly, leisurely, and without risk of interruption or complication to the completion of operations which otherwise were impossible. In like manner, it seems to me, the adoption of aerotherapy as a basis of treatment brings the physician to a vantage ground in respect of therapeutic possibilities from which he is debarred under the more protective system. Let me urge that to place a patient suffering from pulmonary tuberculosis under the influence of aerotherapy is not synonymous with the adoption of expectant treatment. Aerotherapy is, in the *truest sense, a therapeutic* measure which has *been* found capable of giving the **best** results.

was regarded as one of the most dangerous undertakings possible. Nowadays, although we look upon all intestinal work as demanding the greatest pathological knowledge, technical skill, and judgment, we know that it can claim an ever-increasing measure of success. One of the first reasons for this progress lies in the fact that we have now ever clearer conceptions of the functions of the peritoneum. When the abdominal cavity first became accessible to surgical interference our conceptions of it were dominated by the idea that its lining was one of the most vulnerable points in the whole body. But soon after came the gradual recognition of the wonderful powers of repair possessed by the membrane when unsoiled by septic matter. Perhaps no one did more to demonstrate this even before our era than the father of abdominal surgery, Spencer Wells. And we must not forget that this was in spite of the fact that much of his work was done before the acceptance of the Listerian *régime*. With the advent of the antiseptic era and the general improvements in results achieved, the conviction was forced upon the surgical mind that many of the successful cases of abdominal section which had recovered anterior to it could not have been performed under anything approaching ideal aseptic conditions. In other words, it seemed clear that if (as was almost positively the case in many of the earlier operations) a certain amount of infective matter must have been left behind in the abdomen after procedures where recovery followed, the peritoneal cavity surely possessed some, then unknown, power of tolerating a certain amount of septic material for a time and ultimately removing it completely. This conviction was strengthened more and more as the pathology of so-called appendicitis (to mention no other lesion) began during the same period to be better understood, and its clinical history to be more closely followed with and without operation. With the knowledge that this disease was an infective peritonitis starting from the vermiform appendix, it became abundantly clear that unless the peritoneum possessed the power of disposing in some way of very considerable quantities of septic matter no case of *acute* appendicitis could possibly recover. And yet it soon became obvious that many such cases did get well without any operation even after severe peritonitis. Moreover, this led to much greater hopefulness about all surgical interference within the abdomen, whether for accident or disease. And the conviction henceforth gained strength that in the peritoneum we possess a powerful ally, always ranging itself upon our side instead of a foe. These facts gradually aroused doubts as to whether the free use of chemical germicides so beneficial elsewhere was, within the abdomen, really sound practice when it was seen that the peritoneum alone could dispose of infective material and when it was discovered that these germicides could exert noxious influences upon the inherent reparative powers of the membrane.

By degrees bacteriology and biology have furnished us with explanations of the facts observed in clinical study, and we have come to know something more definite about the defensive powers of the serous cavities. We know now pretty conclusively that these defensive agencies are not at an end when the membrane has thrown out a certain amount of plastic lymph for the repair of a lesion or the shutting off of an infected area. We believe that this is not its only function, but that under irritation it pours out an abundant effusion of fluid, diluting any toxins present, and that this fluid, like healthy serum, has besides an inherent property of inhibiting or destroying bacterial growth to a certain extent, limited of course, but marvellous as far as it goes. The observation that the peritoneum was able under proper stimuli to rapidly furnish lymph of the very best quality for the repair of damage was a very old one. But the view that the fluid poured out into the abdomen under traumatic or bacterial irritation was in the first place a diluent of any toxins present, and in the next inhibitory or destructive to organisms, has only come to us recently in the evolution of biological knowledge.

Its development has gone hand in hand with the study of phagocytosis, and cytolysis, and of antibodies and opsonins in the blood and fresh serum. And I cannot help feeling that these studies have not as yet sufficiently influenced our practice in dealing with the peritoneum. Immense industry and brilliant research have led very far and have furnished us besides with antitoxins and vaccines for a number of infections. But, speaking with the most profound respect and gratitude for these discoveries, I sometimes venture to think that attention has been more or less diverted by them for the moment from the marvellous powers of the body itself of producing antibodies *in situ* when called upon. For instance, where infection of the peritoneum is obvious, some of us are perhaps nowadays too ready to turn to manufactured antitoxins and to overlook the fact that before they were discovered countless cases had been saved by some germ-destroying mechanism inherent in the serous cavities themselves, probably in the serum and cells effused into them during inflammation. After all, the practice of increasing the amount of blood and serum in a damaged part by means of poultices, fomentations, and other so-called rubefacients is of great antiquity, and has been universally sanctioned as a means of combating destructive inflammation. But the biological mechanism, so to speak, by which hyperæmia operates in arresting septic processes has only recently received close study, as I have said. At all events, we are not so much afraid now as formerly of hyperæmia and effusion into serous and other cavities within certain limits. Indeed, under the influence of Bier's views on hyperæmia the premeditated increase of blood-flow and effusion of serum in infected areas has once more come to be emphasised as a regular practice with the very best results, as, for instance, in infective synovitis of joints and tendon sheaths. Here it has been proved over and over again that joint cavities swarming with certain bacteria beforehand are sterile after the hyperæmia treatment with rubber bandages or suction glasses has been properly carried out at intervals for a few days. That inflammatory effusions into the peritoneal cavity under septic irritation are also, up to a certain point, beneficial seems now certain. And this view explains why it is that we now very often obtain so much better results in abdominal surgery without drainage in cases where a few years ago it was considered indispensable and carried out very elaborately.

It is, of course, necessary to be very cautious in applying these theories to our practice in the surgery of the intestines, but we have, I believe, already received much valuable help from them just in this particular field. We have learnt to be more rigorous in our precautions for warding off sepsis from without during operation, more careful to guard the serous surfaces from all rough treatment during manipulation, and from chemical or physical irritation while exposed, and, on the other hand, more hopeful and bolder in cases where it is already obviously present within the abdomen. Let me illustrate this now by a case. About a year ago I was asked by my colleague, Sir Thomas Barlow, to operate on a boy aged 14 years who had been ill for some weeks with peritonitis, which had ultimately culminated in a localised swelling in the left iliac fossa, probably tuberculous in origin, and already softening into an abscess. With considerable misgiving, knowing from experience the softened condition of tuberculous intestines around a breaking-down mass, I operated. A foul, stinking collection of pus was found in the midst of adherent coils of small intestine thoroughly rotten. An attempt to separate them only resulted, as I had feared, in their crumbling down in several places. It was necessary to resect completely a considerable length of this small intestine ragged with holes and to join sound bowel end to end above and below the damaged portion, all of which was removed. Now all this was done without antiseptics in the presence of foul pus which we could not pretend to have completely evacuated and wiped away during and at the end of the operation. Notwithstanding, I thought it better to close the parietal incision without drainage, even at the risk of the effusion re-forming and pointing through the closed wound. This it did to a small extent after some days, but the discharge soon ceased, the wound healed soundly, and the boy made a complete recovery, being fat and ruddy and without any intestinal trouble when he returned for examination some months later. Not so long ago such a condition as was found here would, I confess, have seemed, at all events to me, hopeless, and would have been treated by simply drawing out the ragged, perforated bowel and making an artificial anus in it, with the usual bad result. But the boldest course proved the best, in spite of the septic condition encountered. It may be asked, Would it not have been better to put in a gauze drain down to the line of junction in the intestine? Possibly it might have been for a day or so, but I thought not at the time, and am of the same opinion still. The presence of effused serum after such an operation is not injurious within certain limits, and it is not necessary to drain it off in every instance. This requires judgment, and each case must be treated on its own merits.

I may be pardoned for alluding to two other cases bearing on the same point. As they have both been recorded, a brief notice will suffice. The first was that of a woman, aged 76 years, admitted into University College Hospital in a very serious condition, due to an internal strangulation of several feet of intestine by a band, with gangrene of some feet of it. On opening the abdomen, a couple of pints of very foul, dark, greenish-brown fluid escaped, and black dead coils of intestine followed. I found it necessary to resect 5½ feet of bowel to reach sound gut. No antiseptics and very limited mopping were used, and the edges of the wound, which had been soaked in the foul effusion throughout the operation, were united without drainage after being simply wiped dry. Primary union, not showing a single flaw, was the result, and I saw the patient two years afterwards, at the age of 78 years, quite well and hearty. She was an Ulster woman, which may, of course, have accounted for her vitality. The second case was like it in almost every respect. It was that of a lady, aged 49 years, to whom I was hurriedly called out of London 18 months ago. Here, too, there was a disastrous sudden internal strangulation by band of about 20 hours duration. The patient was cyanosed and pulseless at the wrist. When the abdomen was opened about 1½ pints of stinking, greenish-brown fluid gushed out, and a mass of black foul intestine was found to be hopelessly strangled. It was necessary to resect 4 feet 9 inches of bowel and make a side-to-side anastomosis. Here, too, the parietal wound was completely closed without drainage or the use of any [illegible] aled in ten days with only [illegible] y, in short, was perfect and [illegible]

In neither of these two cases could there be any pretence that the abdominal cavity was left quite clean by simple mopping at the end of the operation. But in both the peritoneum was manifestly able to deal with what septic matter remained behind after the removal of the gangrenous intestine and the bulk of the effused fluid. The most reasonable interpretation of the results appears to me to be that the effused fluid was, in the first place, inhibitory to the free growth of organisms, and in the second a diluent of the toxins of those present, enabling them to be excreted without harm to the system generally and to the kidneys in particular. I feel confident that without a belief in the newer views as to the powers of the tissues to deal with considerable quantities of certain septic matters I, at least, would have regarded these three cases as hopeless and would have abandoned them when I saw the state of things within the abdomen. Other cases similar to them might also be cited if time permitted. Moreover, I feel sure that any prolonged attempts to render the abdominal cavity more ideally clean either by flushing by antiseptics or sponging out—such as would have been made a few years ago—would have been not only futile here, but injurious to the defensive works of the peritoneum. In these cases we were dealing with intra-abdominal conditions undoubtedly contaminated. It was our business to restore the continuity of the obstructed and damaged bowel, and by every conceivable precaution of asepsis to prevent any superadded infection from without. This we did and evacuated the bulk of the foul matter. With what remained the peritoneum was able to deal, and did so rapidly.

We are here thrown back upon the faith of our fathers in the *vis medicatrix Naturæ*—a power intangible, beneficent, all-pervading, claiming our faith, arousing our hope, but baffling our analysis hitherto beyond a certain point. Yes, we have changed our conceptions of the protective and reparative functions of the serous membranes very much indeed within the past few years, and, as a rule, to the advantage of our patients. We recognise and understand their protective purposes more fully, and are careful to foster and not to impede them. Who would have believed a decade or two ago that the brain and cord may be bathed in virulent septic fluid for days, and yet recover all their delicate mechanism once more, aided by manufactured antitoxins introduced from without? And none have demonstrated this fact more satisfactorily than the physicians of Belfast in your terrible epidemic of cerebro-spinal meningitis. Again, the fact established by numerous observers now that this same disease in its severe forms may be recovered from under simple repeated tappings of the spinal canal through the lumbar sac without any injection at all suggests strongly that these serous coverings, too, must possess defensive works of the highest order, only requiring slight assistance in the removal of an overplus of poison to effect a complete recovery in many cases. And this does not apply alone to infection with Weichselbaum's bacillus. Those of us who, like myself, have seen our patients in a state of wild delirium, &c., from cerebro-spinal meningitis starting in the ear, relieved almost at once and ultimately recovering completely after repeated withdrawal from the lumbar sac of the products of inflammation, are driven to the conclusion that the powers of defence against bacterial invasion possessed by this cerebro-spinal serous membrane must be very great, and analogous to that of the peritoneum.

Once the assurance was arrived at that the serous membranes were on the side of the surgeon and not against him, a long step in advance had been made, and we were encouraged to put forth every power to preserve all their protective forces intact. For it became a matter of observation that these could, under certain circumstances, become exhausted. Prolonged exposure and chill, for instance, or injudicious manipulation or sponging quite apart from sepsis, had been found by experiments on animals and in practice on the human patient to lower the reparative forces of the peritoneum. And besides this, though the peritoneum could be shown to tolerate a certain amount of bacterial poison, it became quite clear that, marvellous as were its powers in this direction, they had their limits, and these could ultimately be reached, even in the case of the less virulent organisms. Also we came to know that there are various infections, for example, with certain streptococci, which seem almost from the first to baffle all the reparative and eliminative powers of the serous coverings. Which of us has not often [illegible] by operation? And which of us has not felt in operating for epityphlitic abscess that we have done little more than provide an escape for pus which had already been securely shut off from the system by adhesions, in spite of the bacteria and their toxins? Which of us, finally, has not seen many cases of severe epityphlitic peritonitis, where we have opened the abdomen early and found only general redness of the serous surfaces, with very slight effusion and no trace of reparative lymph, where deep general toxæmia was already obviously present, and where from the first the peritoneum seemed unable to cope with the poison, either on account of its quantity or, more probably, of its peculiarly noxious quality? We have seen the same thing in many cases of punctured wounds of the intestines. In some, great advances in the direction of repair only calling for a little ordinary surgical help, and in the others no progress at all in the formation of plastic lymph, and a condition beyond the reach of any operative measures. When we speak now of peritonitis we are conscious that we are using a term which includes conditions as widely apart as are an ordinary attack of eczema and a desperate cutaneous streptococcal erysipelas. This knowledge has already had the greatest influence on our treatment of abdominal inflammations. Take, for instance, the question of drainage, formerly considered indispensable. We now know that in many cases it is not only not necessary, but injurious. Many of us are able now in certain cases, where an inflamed epityphlon or pyosalpinx has been removed from the middle of a small abscess, to close the parietal wound without drain and obtain flawless union *per primam*.

Another observation which has had an enormous influence upon the surgery of the bowel is that healthy intestinal walls will prevent the migration to any serious extent of the bacteria of the contents through them, but that if their vitality is lowered (to use an ordinary term) by accident or disease, even without any breach of surface, this migration will take place through mucous, muscular, and serous coats, and the general cavity of the perineum will thereby be infected more or less seriously. This most important discovery —first made upon the fluid found in the sacs of herniæ in various degrees of strangulation and then demonstrated experimentally—has had a greater influence on our dealings with the intestines than is commonly supposed. On the one hand, it prompts us in our operative manipulations to deal as gently as possible with the tissues of the bowel, and, when the latter is damaged by injury, strangulation, or other diseases, to be sure that in removing it we only leave really healthy tissue behind, not merely that which shows no loss of substance, but such as is capable of resisting the emigration of organisms from within outwards. It also prompts us in cases where enterectomy is contemplated, and where time permits, to reduce the number of bacteria in the contents of the intestine by laxatives, enemata, and intestinal antiseptics, as well as by the cleansing of the mouth, teeth, and pharynx, and the use of only sterilised albuminous food. Moreover, it has led us in cases of obstruction to adopt the routine of washing out the stomach thoroughly before operation wherever feasible, knowing as we do, since the practice has been adopted, that in many such cases the stomach contains large quantities of putrid material which in course of time would have to be vomited or pass through the part of the intestine lowered in its vitality by the strangulation, and possibly also by the exposure and manipulation necessary during operation, thus increasing the chances of infection. That a certain limited number of bacteria pass from the intestine into the peritoneal cavity in health without injurious effects seems probable from recent investigations. This suggests the possibility of a gradual immunisation of the serous covering in chronic obstruction—a view which some of the facts observed in this condition seem to support.

Other additions to our knowledge, both theoretical and practical, have also combined to remove many of the risks of intestinal operations. Among these is our experience that patients after such procedures need not necessarily be entirely deprived of food by the mouth for long periods. This, of course, is contrary to the teaching of earlier days. And yet it is in accord with sound theory. We know now that the mechanical efficiency of our deeper line of sutures passing through all the coats of the bowel lasts in most cases for days if cleanly done, and is sufficient to prevent separation by the movements of peristalsis, and that round the outer seromuscular sutures enough lymph is thrown out in six or eight hours to produce fairly sound union and stop leakage. We know, too, that this plastic process is more perfect the better the patient is nourished. And as it is often the case that such patients have been precluded from having proper nourishment for days beforehand, or have constantly vomited it when taken, the need of aliment after operation is very great. Of course, when vomiting due to the anæsthetic is still present, food by the mouth is useless. But we are now able to give peptonised foods by the rectum, which were not formerly at our disposal, and have more recently learnt how to employ several important aliments subcutaneously. Here not only can water, the first need of the system, be given in large amount and with perfect safety in normal saline solution, but also carbohydrates in the form of 5 per cent. solution of glucose. In this way two ounces of sugar can be administered per diem; in short, a very important food, without any demand upon the alimentary tract. The increased action of the kidneys induced by the free *instillation of fluids* we believe to be most useful further in carrying off diluted toxic matters from the system charged with them as a consequence of the condition for which the operation was performed.

Then during the same period what improvements in the art of administering general anæsthetics have taken place! The drugs are now purer, the dosage better formulated, and the danger signals during administration better understood. We now recognise that the anæsthesia must be pressed while the peculiarly sensitive parietal peritoneum is being manipulated, while it may be reduced or actually omitted during the manipulations and stitching of the practically insensitive intestine. The amount of the drug therefore given in these mostly protracted operations is now enormously and advantageously reduced in the hands of experienced administrators. This we owe in a large measure to the recent brilliant demonstrations on the innervation of the parietal and visceral peritoneum by our Swedish and Russian *confrères*. Their discoveries supply us besides with many data of the utmost use in the localisation of lesions in the abdomen by painful impressions. Further, many of the dangerous pulmonary sequelæ of general anæsthesia so often seen not long ago in intestinal surgery, especially when stercoraceous vomiting was present, and before the routine of washing out the stomach before operation was practised, are now reduced in number and severity. Thus infective affections of the lung are avoided or controlled by greater care in cleansing the apparatus employed, and the rigid attention to the antisepsis of the teeth, nose, and throat which is now also a matter of routine. We have also learnt that the lung troubles which so often follow abdominal operations can be prevented, and favourably modified by abandoning as soon as possible the recumbent position formerly thought indispensable after operation, and by placing our patients in the sitting position in or out of bed within a day or two of the operation. This has also probably a favourable influence on that nightmare of abdominal surgery, pulmonary embolism or thrombosis, which, though regarded by most of us as depending on septic conditions, is undoubtedly favoured by shallow respiratory movements in the recumbent position.

Whether the employment of local and spinal analgesia will ultinately eliminate some of the risks following general anæsthesia, it is too soon to predict with any certainty. But from what I have myself seen of both procedures in hundreds of cases, and from the study of analyses of many thousands more now published, I cannot help hoping that there is a great future for both in abdominal and especially intestinal surgery. On one point, however, I believe all surgeons who have employed spinal analgesia to any extent are agreed, and that is that the conditions under which the operations are done with it are immeasurably superior to those present under general anæsthesia. There is, for instance, absolute quietude and relaxation all over the field of operation—no small matter in the patient's interests where delicate adjustment of parts is of importance. At all events, for my own part I have thought it my duty to study the whole question in its many aspects, and to examine into the value of these methods in hundreds of cases guardedly, patiently, and I hope dispassionately. For local analgesia, which is quite innocuous when used intelligently, there is undoubtedly a considerable, if restricted, field of usefulness in abdominal work, as, for instance, in strangulated hernia in the aged and decrepit. Here it is an ideal procedure, and I believe it has already saved many lives by eliminating the well-known risks of general anæsthesia.

Another point which has had a remarkable influence upon intestinal surgery has been brought out within the last few years, partly by experimental work on animals and partly by the experience of surgeons who have felt themselves compelled, for one reason or another, to remove considerable tracts of bowel. We have learnt that considerable lengths of the jejunum, ileum, colon, and rectum can be at all ages removed without any very apparent influence for evil upon the processes of digestion and assimilation. I do not for a moment wish to suggest that we have arrived at final conclusions upon this point. Physiologists are at present hard at work upon it, as I know, and are making extensive studies on the excreta of patients who have been compelled to part with various portions of the alimentary canal. Nor do I wish to acquiesce in the removal of any part of the latter tube for any but the most unavoidable reasons. I merely desire to draw attention to the fact that for some of the gravest emergencies in human experience large portions of the intestinal tube have been removed without seemingly producing the deleterious effects which might perhaps have been expected. My own experience of such procedures includes the removal, in one case, of between 6 and 7 feet of small intestine, in several of between 5 and 6 feet, and several more of lesser amounts of both small and large intestine. In none of these was there any evidence months or years later that the general health had been in any way injuriously affected. And it has been the same in many published cases though not in all. At all events, I believe it has been shown that the removal of any amount of small intestine up to 6 feet can be well tolerated. And, as far as I know from observation and study of the literature of the subject, age or sex does not influence this conclusion. My own eldest case was aged 76 years, and here at least 5½ feet were excised, the patient being in excellent health two years later, as was also another case over 50 years of age in which I removed 6½ feet. How much of the large intestine can be removed without demonstrable effects on the health is not yet fully known, but for malignant and tuberculous affections nearly the whole has been taken away or excluded from use, and the patients have enjoyed good health afterwards. I have recently seen one of my own cases in which more than five years ago I extirpated a great part of the colon for malignant disease and excluded the rest, and the patient is now in the most robust health, and without any sign of recurrence, with only the rectum representing the large intestine. A full report of the effects on the excreta of the elimination of the colon in this case will soon be published from the chemico-pathological laboratory of University College. But it is, in my opinion, quite another thing to say that the large intestine should be removed for other less serious conditions, such as chronic constipation. Personally, I have no experience of the procedure for this trouble, and am not concerned with the controversy anent it.

Having reviewed some of the factors contributing to our present success in intestinal surgery, let us glance at some of the conditions formerly considered desperate which have been actually relieved during the last decade or two. Among the injuries, punctured and bullet wounds and bad contusions of the bowel have been successfully dealt with; gangrenous strangulations, external and internal, with or without the removal of long pieces of bowel, have been saved; large sarcomata involving intestine have been extirpated; tuberculous tracts of intestine in a hopeless condition of ulceration have been taken away with transient or permanent relief; typhoid ulcers and perforations have been excised, and though only a small percentage of the patients afflicted with them have been saved, owing to the general condition, we must remember that the best authorities tell us that the mortality of typhoid perforation treated without operation is 98 per cent. Intussusceptions operated on at a reasonably early stage are now almost invariably successful.

But perhaps the greatest achievements of intestinal surgery have been those gained over the terrible cancers of the bowel, so hopeless and so distressing until quite recently. If we had learnt nothing more about these than that they could in most cases be successfully short-circuited, and that the patients could thereby be relieved of the immediate dangers of obstruction without the sad necessity of a permanent artificial anus, with all its bodily and mental distress, we should have won an immense boon for a class of sufferers who claim our sympathy almost above all others. But the last few years have taught us far more. We have seen that cancers of every part of the large intestine, from the cæcum to the anus, can be removed with immediate success and with, at all events, as much prospect of non-recurrence as those of other parts; perhaps even greater. Indeed, this ought to be so, seeing that we are dealing in most cases with columnar epitheliomata of a low type of malignancy whose mode of lymphatic extension is through tissues well defined and accessible, and better understood, anatomically, than any other. In any case, the gain of several years of life, which is common now, is an enormous one, especially as the objectionable artificial anus is becoming rarer and rarer.

The greatest advance of all, however, is in the direction of dealing with those terribly distressing conditions due to cancer of the lower part of the large intestine. Since it has been demonstrated by countless cases that carcinomas of the pelvic colon and rectum, unapproachable only a few years ago, can now be removed with a good prospect of prolonged immunity from recurrence, if no more, a great load has been taken off the surgical mind. We owe to Kraske and his followers a great debt for the gift of the trans-sacral operation for the removal of cancer of the rectum. We owe him perhaps more for the working out of the combined abdominal and dorsal procedure which he has recently advocated for some cases as a substitute for his original trans-sacral method, the defects of which he has recognised and frankly acknowledged. And as its principles and details become more and more familiar and the selection of cases follows the usual course our gratitude will, I believe, deepen. In this procedure we have not only the prospect of excising the original growth anywhere between the anus and descending colon and preserving the anus in all its functional integrity, but also of removing those parts of the retroperitoneal tissues which contain the lymphatic vessels and glands likely to be, if not actually, infected with malignant elements from the growth. Herein we are only following the principle recognised now as indispensable in all operations on cancer, whether of the tongue, breast, or other organ—that is, that it is not only necessary to the highest ideals of success to extirpate the original cancer, but also all those tissues around, in which the lymphatics run, whether visibly or tangibly infected or not. This combined method of operating on the pelvic colon and rectum is, of course, a severe procedure, and at present has a high mortality for several reasons, mostly those due to faulty technique and inexperience in the selection of proper cases. But if in the hands of the best surgeons who followed Kraske in the first few hundreds of ordinary trans-sacral operations the mortality was over 30 per cent., and has fallen since in the hands of some experts, each with an experience of several hundreds of operations, to about 10 per cent., we may surely hope for a corresponding improvement in the immediate results of the abdomino-dorsal method as it is better understood. Of the superiority of its functional results over the sacral methods there can be no question. And as to the greater immunity from recurrence we have every reason to believe that it will be proved when we have larger numbers from which to judge after years of observation. And with so formidable and painful a malady there are numerous sufferers who would be prepared to face some extra risk from an operation which offered a larger hope on the two points of function and non-recurrence. And we must not forget that a new source of accuracy of diagnosis has come to us in the use of the Roentgen rays acting on meals mixed with bismuth and other substances. This method of examining the state of the bowel seems to promise in the future to patient and surgeon alike a large measure of help.

I have tried now to give a short review of the gradual evolution of intestinal surgery from the point of view of one who though still in his fifties has seen it in his own time. This evolution has not been the result alone of the better conception of asepsis, much as we owe to it. Nor has it been due altogether to improved manipulative skill. It has resulted from clearer views on the vital processes concerned in all lesions within the abdomen. These we have gained partly from closer clinical observation, aided by what we have learnt from the anatomist, the pathologist, bacteriologist, biologist, and physicist, and from careful sifting of our experiences, whether of failure or success.

Looking back, as I have tried to do here, and looking forward, as every hopeful man must and ought to do, we see encouragement in both directions. What has been done within the last few years in this important field of surgery, in spite of the enormous difficulties which surround it, assures us of a far greater yield in years to come, working, as we shall do, under more favourable conditions and with ever-increasing knowledge. Is any inclined to despond, thinking, mayhap, of the magnitude of the problems still unsolved and the smallness of his own individual powers of grappling with them, let him listen to the clarion note which rang out just one hundred years ago from one ranking among the greatest philosophic thinkers of his day and certainly its greatest poet:—

> “[illegible]
> [illegible]
> [illegible]
> [illegible]
> [illegible]
> [illegible] rong.”

This appeal has since then been finely responded to by his own countrymen, though at the time almost crushed materially and inclined to be despondent. Let us see to it that we, too, undeterred by the languid interest in science of a commercial and materialistic age, press ever onward, thankful for past achievements in the interests of suffering humanity as we look backward, hopeful and courageous as we look forward to the years to come.

FOOD ADULTERATION.—The annual report of the Bristol city analyst and bacteriologist for 1908 states that during the year there were 1303 samples of food and drugs submitted for analysis. Of these 1170 were genuine and 133 were adulterated, the latter including 101 samples of milk, 15 of butter, six of margarine, and five of spirits. In 1907 there were 1300 samples examined and 122 were found adulterated.

CHRONIC "RHEUMATIC" MYOSITIS (MUSKELSCHWIELEN),

WITH CASES SHOWING SOME COMMON ERRORS IN DIAGNOSIS.

BY N. S. YAWGER, M.D.,

ASSISTANT PHYSICIAN IN THE DISPENSARY FOR NERVOUS DISEASES IN THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

I FIRMLY believe that the most frequent cause of the so-called "gouty" or "rheumatic" pain is a form of chronic myositis, and surely suffering which is so widespread and which will in most cases yield to appropriate treatment demands our attention. These muscle deposits have been recognised and successfully treated abroad in the Germanic countries for more than 35 years.

At the January meeting of the Philadelphia Neurological Society of this year, in a paper on "Indurative Headache,"[1] I called attention briefly to these general muscular thickenings. While reading the references for that paper I was amazed to learn of the frequency of the development of chronic myositis in muscles other than those of the head and neck, and my attention was also attracted to errors in diagnosis to which this condition has given rise. As early as 1843 Froriep[2] recognised the condition, but the first important contribution to medical literature upon this subject is by Uno Helleday,[3] a Swede, who, in 1876, wrote extensively about this matter and reported eight cases showing that lesions occur in various parts of the body, all of which he treated successfully. The article finally ends as follows: "The object of these histories and what has gone before is to impress you with the importance of carefully examining the musculature of many cases which present a picture other than that which you usually understand as muscular rheumatism." Gowers,[4] under the heading of "Neuro-myositis," writes without being at all definite about the subject, but he evidently recognises that it is important when in closing he says: "The influence of gout, including ancestral gout, is a subject upon which the young practitioner starts with a high degree of scepticism regarding the teaching of his seniors. But year by year his doubts become fewer and fewer, as they are rubbed away, or removed more sharply, by contact with fact." Because of the thoroughness of Gowers's writings, I mention his book to show that this subject has made almost no headway among the English-speaking people since its careful study by the Scandinavians more than 35 years ago.

Among the causes affecting this condition is heredity, there being a distinct family tendency to these diseased muscles. The effects of climate and weather are most marked. In a case of indurative headache which I have reported the patient found the damp, foggy weather of England very annoying, but he was happily free from suffering while travelling in Switzerland. Chilly and rainy weather often causes the indurations to become painful; it is sufficient to be within the outer limits of storm conditions and not necessarily within the area of rainfall. They may appear at almost any time of life. I have recently observed temporarily infiltrated muscles in the neck of a child of two years and they are common in old age. While probably no voluntary muscle enjoys an immunity there are sites of predilection, the most common of which is in the muscles of the head and neck. This, I believe, is due to the exposure through lack of covering, to which this part of the body is necessarily subjected. The gluteal, lumbar and deltoid regions, and calf muscles are often involved. The muscles may be invaded at their points of insertion, as in those attached to the superior curved line of the occipital bone and those inserting into the processes of the upper cervical vertebræ, or the infiltrations may appear within the bodies of the muscles as is frequently seen in the abdominal walls, and in the sterno-mastoid muscles near the level of the thyroid cartilage. At times the infiltration extends to the periosteum to which the muscles are attached and also to the fascia.

The pathology of these diseased muscles is largely hypothetical for the reason that people do not die from this condition. By some it has been thought to be of nervous origin, but Vogel, quoted by Bum,[5] in sections from rheumatic muscle found thickening and adhesion of the neurolemma to the nerve branches supplying the muscles, a finding which does not strengthen the neurogenous hypothesis of this condition. Oppolzer,[6] from his studies, believes the lesions are not inflammatory in character, a view which does not coincide with that of Helleday. The muscle infiltration may be due to the deposition of an excess of the salts of uric acid or an allied substance, with the later formation of connective tissue. I have known vigorous massage treatment of a patient with extensive indurations to be followed by an attack of acute muscular rheumatism. It seems probable that this formation of indurations is a manifestation of a metabolic disturbance autotoxic in character. At all events it appears that as soon as good circulation is established relief is at once experienced. Whatever this muscle poison is, many of its subjects have had bilious attacks in childhood, and in advanced life they often suffer from arteriosclerosis.

These infiltrations or myisitides (the Germans prefer myitides) may "make up" over night; they are frequently absorbed but tend to recur. After appearing again and again at the same point they finally become chronic and then vigorous treatment is necessary for their removal. The enlargements present a different feeling upon palpation, depending largely upon their duration; the longer they exist the firmer they become and the more resistant they are to treatment. Those of recent development are known as *swellings* and feel doughy to the touch; others because of their firmer consistency are spoken of as offering resistance; and finally those of long standing show cartilage-like thickenings and are known as *indurations*. They also vary in size and in the intensity of the pain which they occasion. There may be a diffuse and extensive infiltration which causes but little inconvenience and which may not manifest itself except during action of the involved muscle, as is seen in the milder cases of lumbago. Again, small patches may give rise to frequent and excruciating pain and this is not unusual in the abdominal muscles, where shot-like enlargements are often found.

It has seemed in what I can gather from the literature and by my own personal experience that these deposits may develop under the following conditions: in muscles that are overworked, as in some cases of writers' cramp[7] and other occupation neuroses; in those that are not sufficiently exercised; in muscles that are much exposed, as in those of the head and neck; and, finally, where an injury has been sustained, which is frequently the case in the back. The symptoms are those of pain which may be sharp and cramp-like, or there may be an aching sensation upon use of the diseased tissue. Instead of pain there is at times paræsthesia at some distance from the deposit, as in a patient seen by Norström[8] in Paris who had for years complained of the sensations of cold, numbness, formication, &c., in the thumb and two adjoining fingers of the right hand, and which upon examination presented a big lump in the deltoid muscle which pressed upon the radial nerve without giving any special abnormal manifestation in the muscle itself. There is often muscle insufficiency. Upon pressure made with a friction movement there is tenderness, but firm and steady pressure often affords relief. If the swollen muscle impinges upon a nerve trunk or nerve fibre a true neuralgic pain will result. There may be diminished or absent elasticity; finally, the presence of a palpable thickening in the muscle; fever and redness are absent. There are often associated symptoms in various parts of the body, some of which are depression of spirits, mental torpor, unnatural drowsiness, marked susceptibility to cold, torpidity of the liver, indigestion, painful spasms of the calf muscles, paræsthesia, general myasthenia, pyorrhœa alveolaris, and hypersensitiveness of the teeth.

To those familiar with muscle conditions I know of but one lesion that is likely to be mistaken for an induration, and that is a gumma. Indurations are exceedingly common; there is a history of chronic rheumatic pains; as a rule they are less sharply defined; there is pain upon pressure with friction, and they yield [illegible] in muscles are relatively ra[illegible] attended by other evidence [illegible] antispecific medication.

The mistakes in diagnosis to which those rheumatic deposits give rise are very numerous. Many cases of cephalalgia are of this variety[9]; involvement of the intercostal muscles has been taken for intercostal neuralgia and pleurisy; i[illegible] ute and chronic appendicitis [illegible] pelvic adhesions, calculus of [illegible] involvement of the gluteal [illegible] t disease; in the neck they have been mistaken for swollen glands; the frequently complained of growing pains in children I believe are due to this condition, since the healthy growth of a child should not be painful.

I shall allude briefly to a case reported by Kleen[10] which was at first thought to be one of gastric ulcer. The patient was a female, aged 23 years, single, who for more than a year had suffered from pain circumscribed at a point over the gastric region a little to the left of the median line. The pain was constant but worse after meals. There were other slight symptoms of indigestion. Upon palpation a distinct difference in the consistency of the upper portions of the recti abdominales muscles was made out, the left being the harder and the more extensively infiltrated. At this area careful lateral pressure caused sharp pain which evidently had its origin in the muscle. When she endeavoured to rise without the assistance of her hands the pain was intensified at this point. The patient recovered under less than a month's massage treatment.

I have myself encountered indurations in the abdominal muscles and know of a Philadelphia woman who for a long time had suffered from sharp attacks of pain in the abdominal region. During a trip abroad she had an attack of unusual severity. A physician was summoned, a diagnosis [illegible] te operation was [illegible] of milder attacks [illegible] to submit to the [illegible] lay or so the pain [illegible] hia her condition was recognised as being due to deposits in the abdominal muscles. Through a course of massage the diseased muscles were restored to normal, and while she still has her appendix she no longer has the abdominal pains.

Moderate distension of the abdomen with gas is very common, and with the abdominal muscles in this indurated condition it takes but slight distension to cause stretching of the diseased muscle fibres, thereby causing pain. In some of the cases where normal appendices are found at operation it is the abdominal muscles that are at fault. I have recently examined the abdomen of a physician while he was having an attack of colicky pain. He was subject to mild attacks of this kind and stated that some time before he believed that he had an attack of appendicitis, but that an examining surgeon advised against operation. I found his abdomen slightly tympanitic and the abdominal muscles infiltrated and very tender. The pain was relieved by firm, steady pressure. Some of the muscles of the head and neck were hypersensitive and he often suffered from headache. Within a few hours the distension subsided and the pain ceased. I think it very unlikely that his appendix had at any time caused the abdominal pain.

I am aware of the incredulous attitude of orthopædic surgeons towards a rheumatic condition about the hip-joint of a child, but the condition surely exists at times, and there are a number of cases in literature where rheumatism has been mistaken for incipient tuberculosis of this part and the child has been placed upon extension, while a later diagnosis was followed by proper treatment and prompt recovery. This may account for cases of hip-joint disease reported as cured without shortening and with perfect motion. Many cases of early hip-joint disease are diagnosed as something else, and the fact remains that a few cases of lameness with rigidity of the muscles about the hip and pain around the hip and knee are rheumatic and should be recognised and treated as such.

The following case was referred to me by Dr. Ralph Butler in April of this year. The patient was a dressmaker, aged 38 years, in whom the present trouble began 14 years ago with an intermittent grumbling pain in the right lower jaw. Six weeks later she had a severe attack with pain extending into the right ear and back part of the right side of the tongue. The year following the attacks became frequent and quite severe. At times several months would pass without paroxysms; again they might occur every five or ten days and persist for days or even weeks. The neuralgia would often begin with frequent and mild attacks, then recur more often and be of greater intensity. At times when asleep she would be awakened by such an agonising attack that she would cry out with pain. She has walked the floor for hours with her hand pressed as forcibly as possible against her face. For a week at a time her face has been so painful and stiff that she had to limit herself to a liquid diet. There were occasions when it was almost impossible to avoid provoking attacks, they being caused by passing a comb ever so gently through the hair, the slightest breath of cold air, brushing the teeth, putting out the tongue, or even attempting to speak. The paroxysms would start with just a few twinges of pain; these would increase, and then the most agonising suffering would ensue. Attacks would last for almost a minute, recur again and again, and finally cease, leaving the patient almost exhausted. During the most severe attacks the affected side of the face would suddenly become flushed and the eyeball injected; this would pass away with the paroxysm. During the most severe attacks the pain would extend into the orbital cavity. Her oculist was consulted yearly in the hope of obtaining relief, six teeth were extracted, but all without improvement. Three years after the beginning of the attacks the facial muscles began to twitch; this was relieved by an injection of alcohol. A year ago a neurologist was consulted, who said that the Gasserian ganglion should be removed at once. In addition to the neuralgia there had been headaches, which were very severe and of late had become almost constant. There was much pain in the back of the neck and at times the scalp was very sensitive. She had frequently suffered from rheumatic pains in different parts of the body, especially in the right arm and about the right hip, where infiltrated areas were present. The neuralgia, headaches, and bodily pains were all worse in damp and stormy weather. A year ago she was obliged to give up her work for six months, and this spring her suffering was just as great.

On examination the patient was anæmic, with an anxious expression, and presented the appearance of one who had undergone great suffering. The scalp was thickened and hypersensitive, with especially painful areas over the trapezius muscle and in the supraorbital region on the right side; these areas were indurated, as were most of the trapezius and other muscles [illegible] There was also involvement [illegible] the neck, especially at their [illegible] processes of the upper cervical vertebræ. The [illegible] part of the face was along the upper lip just [illegible] It would take but the slightest touch at this [illegible] a paroxysm. The small facial muscles [illegible] painful upon the affected side.

I made a diagnosis of trifacial neural[illegible] of peripheral origin, involving the three [illegible] and indurative headache. Local tre[illegible] manual massage and rapid vibration [illegible] motor was advised. After a few [illegible] attacks of neuralgia ceased, thou[illegible] ue pressure over the hypersensitive [illegible] of ments per week for two mont[illegible] ce, [illegible] of [illegible] to [illegible] w not been complete. The[illegible] es [illegible] te [illegible] e

[illegible] and I hope [illegible] now live [illegible] ns. [illegible] eights. [illegible]

CASE OF MISSED LABOUR TREATED BY ABDOMINAL SECTION.

BY C. E. PURSLOW, M.D. LOND.;
HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

IN THE LANCET under date of June 26th is an account of a case of missed labour by Dr. Peter McEwan of Bradford, in which he makes the suggestion that some cases of this kind would be best treated by abdominal section. This prompts me to send you an account of a case in which I carried out this line of treatment and which is, I believe, in some respects unique.

The patient, aged 33 years, was admitted to the Queen's Hospital, Birmingham, on Sept. 19th, 1907, with the following history. She had been married 12 years and had had four children and one abortion; the latter was an instance of missed abortion, and the circumstances are so unusual that I may be pardoned for narrating them. On that occasion she came to the Queen's Hospital and stated that she was passing "bones" per vaginam. As the uterus was large she was admitted on Nov. 16th, 1905. On inquiring into her history it was found that her last menstrual period had taken place in May; subsequently she had considered herself pregnant and for three months there was complete amenorrhœa. Irregular losses then came on and continued until admission, and for some weeks she had passed an occasional bone. The uterus was found to be of the size of a three months' pregnancy. The patient was anæsthetised, the os dilated by Hegar's dilators, and a mass of fœtal bones was removed by ovum forceps and flushing curette. These were carefully examined by Dr. A. E. Remmett Weaver, obstetric house surgeon, and were found to comprise almost the entire skeleton of a three to four months' fœtus. She made a good recovery and went home at the end of a fortnight.

After leaving hospital the patient menstruated regularly, the last period occurring on Sept. 16th, 1906. From that date until her second admission, a period of more than 12 months, there had been no sign of vaginal hæmorrhage. She considered herself pregnant, and in February felt fœtal movements; these continued up to June and then entirely ceased; since that time she had suffered from a rather severe constant pain in the abdomen from which she was very anxious to be relieved. On examination she was found to present the signs of full-term gestation, but there was very little liquor amnii, and the uterus was hard and felt as though it were in a continual state of tetanic contraction; it was tender on palpation. The cervix was not typically softened and the os was closed. Two days after admission she was placed in the lithotomy position under anæsthesia with the intention of dilating and evacuating the uterus; it was found impossible to pass a Hegar's dilator into the uterus and the same was the case with the uterine sound. I was at a loss to explain this and suspected a fibroid in the lower segment. I therefore opened the abdomen and removed the uterus by panhysterectomy. The wound healed by first intention and the patient made a good recovery.

The uterus with its contents was submitted to Dr. Leonard G. J. Mackey, pathologist to the hospital, and he reported as follows: "The uterus is closely moulded to the fœtus; there is barely an ounce of somewhat turbid liquor amnii. The fœtus is the size of a full-term child and, judging by the general appearance, the length of the nails, and the amount of hair, it appears to be fully developed. The skin is of a dirty-brown colour; the cuticle, wrinkled and easily detached, is covered in parts with a cheesy substance which is deep yellow as if stained with bile. The bones of the skull are loose and move easily as one presses on the scalp. The wall of the uterus is about half an inch in thickness; the muscle is pale and easily splits into layers. The placenta is situated almost centrally over the internal os and lines the lower two-thirds of the uterus; it is of very firm consistence. A thin grey membrane separates the uterus from the placenta and remains attached to the former when the latter is removed. The specimen is quite odourless. Microscopically, the placenta shows a finely scattered calcareous deposit, the villi have undergone hyaline degeneration, and there is old thrombosis of the intervillous sinuses. There is a considerable amount of fibrous tissue scattered among the muscle fibres of the uterus, but the muscle itself does not show any marked change. The walls of the arteries are thicker than usual, many of the large blood spaces are filled with old thrombi, and, in some, organisation of the thrombus is well marked."

Missed labour is by all authorities regarded as a very rare condition, and its occurrence in a case of complete placenta prævia is, I think, unique. I have made an extensive search but have been unable to discover any record of a similar case. The obstruction caused by the tough placenta explains the inability to pass the sound or dilator into the uterus.

Birmingham.

A CASE OF

INCARCERATION OF THE VERMIFORM APPENDIX CONTAINING A FOREIGN BODY (PIN) IN THE SAC OF AN INGUINAL HERNIA IN A CHILD.

BY THOMAS H. KELLOCK, M.C. CANTAB.,
F.R.C.S. ENG.,
EXAMINER IN SURGERY, UNIVERSITY OF CAMBRIDGE; SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, ETC.

IT is not at all an uncommon experience to find the vermiform appendix as the occupant of the sac of an inguinal hernia, nor can the lodgment of a foreign body in a child's appendix be regarded as a very rare event, but the combination of these two conditions which occurred in the following case must be rare, and would seem to make the case worthy of record.

A male child, two years and four months old, was recently admitted under my care at the Hospital for Sick Children, Great Ormond-street. He came of a family in which there was no history of either tuberculosis or syphilis and had had no previous illness. The first indication that there was anything wrong was about six months previously, when the mother accidentally noticed that he had a small hard swelling in the right inguinal region. She stated that it seemed to be neither painful nor tender, and did not seem to cause the child any inconvenience. From that time onward she thought it increased slowly in size, but it never disappeared even when the child was asleep. He had not been sick, and the bowels had acted regularly. For the fortnight before admission he had not taken his food as well as usual.

On admission the patient was an undersized delicate-looking child. Just outside the external abdominal ring on the right side a tumour of about the size of a filbert could be seen and felt, oval in shape, very hard, especially at the lower end, attached apparently to the subcutaneous tissues, irreducible, and without impulse when the child cried or strained. It could not be moved independently of the spermatic cord, although traction on the testicle did not have much effect on it. The testicle and spermatic cord below the swelling were normal, and examination of the abdomen revealed nothing suggestive of tuberculous disease of the peritoneum. Examination of the chest showed some dulness at the base of the right lung, where the breath sounds were weak. As the swelling in the groin did not seem to cause the child any inconvenience, operation was delayed on account of the condition of the chest. Here about 14 days later definite signs of fluid showed themselves; the pleura was opened and a quantity of pus was evacuated. Bacteriological examination of this showed it to contain streptococci and a pure culture was obtained. The empyema was nearly a month in closing. At the end of that time the child's general condition had very materially improved and it was decided to explore the tumour in the groin which had remained practically stationary in size.

On making a longitudinal incision over the tumour it was at once seen that there was a good deal of infiltration of the subcutaneous tissues. After separating some of the adherent parts the tumour was isolated; it was found to have a pedicle leading up through the external abdominal ring and to be intimately connected with the spermatic cord. The front of the tumour was densely hard, but posteriorly it was soft, and on making an incision behind it was found that a sac had been opened and immediately under the incision the proximal end of the vermiform appendix was recognised. On attempting to draw this out it was found to be adherent at its distal end, but traction on the proximal end brought down the cæcum. With some difficulty the appendix was divided close to the cæcum and the latter returned to the abdomen. The rest of the tumour was then removed, the neck of the sac being transfixed and tied and the abdominal wound closed.

On examining the mass that had been removed it was found to contain the whole of the vermiform appendix; the proximal portion was healthy, but the distal end was much thickened and intimately adherent to the wall of the sac. It was found to contain an ordinary pin which was lying almost transversely to the lumen of the appendix; the point had perforated all the thickness of the wall of the appendix and was implanted in the wall of the hernia sac and surrounding tissues. There was no pus either in the lumen of the appendix or in the surrounding parts. Slight suppuration occurred in the superficial part of the wound, but this rapidly healed, and the patient was discharged in good health just a month after the operation.

It can only be a matter of conjecture in this case whether the impaction of the pin in the appendix or the descent of the latter into the hernia was of primary occurrence. The fact that the mother had never noticed any swelling in the situation of the hernia before she discovered the hard lump there would, perhaps, point to the probability of the pin having been in the appendix before this descended into the sac. It must also be a matter of doubt as to whether there was any causal relation between the perforated appendix and the empyema. The extraordinarily little discomfort which the condition caused the child and the absence of actual suppuration when the wall of the appendix and that of the hernia sac were both perforated by the pin seem rather noticeable features in the case.

A CASE OF ANGIO-NEUROTIC ŒDEMA ASSOCIATED WITH CIRRHOSIS OF THE LIVER.

BY S. G. CORNER, M.A., M.B., CH.B. EDIN.

A MALE patient, aged 40 years, consulted me in the latter end of 1908 for swelling of both ankles and pain which prevented him from walking. He had suffered from this condition for three years. On examination I found œdema of both feet and ankles, which were tender on pressure. All the veins of the lower extremities, together with the superficial abdominal veins, were varicose and distended, and an enlarged vein was present in each axilla. Slight enlargement of the liver was evident, and I had reason to believe that some degree of cirrhosis of that organ was present. The heart and lungs were normal. There was nothing notable in the family history or previous illnesses of the patient except that about three years ago he sustained a fracture of the tibia, from which time he dates his œdema and varicose veins. The urine was normal.

Under rest, total abstinence, and Scott's dressing applied to the ankles he recovered in three weeks and was able to walk without pain. About a month later, while in bed, his upper lip suddenly swelled up. He came to me the next morning and showed a tense swelling in the left side of his upper lip. The swelling subsided during the day, but next night his lower lip became similarly affected, and a swelling developed in the neck. Night after night a lump appeared in a new place. Once the whole tongue was swollen up, so that he could not protrude it. On another occasion the scrotum became tense and œdematous. The back, the buttock, and the arm—in fact, any region—was liable to become the seat of a sudden swelling, varying in size from that of a hazel-nut to that of a hen's egg. The tumours generally appeared at night and were preceded by slight itching.

I regarded the case as one of angio-neurotic œdema and gave him 10 grains of calcium chloride three times a day, increasing the dose to 20 grains. Whether as the result of this treatment or not, the swellings appeared at longer intervals, and in about a month he finally had no swellings at all. He has now been perfectly well for four months, though he still retains varicose veins of the lower extremities and on the surface of the abdomen.

Coggeshall, Essex.

THE PLACE OF THE POOR-LAW MEDICAL OFFICER IN A UNIFIED COUNTY MEDICAL SERVICE.[1]

BY MRS. SIDNEY WEBB, D.LITT.

I HOPE that I shall not be considered impertinent if I venture to say that of all the branches of the public service that of the Poor-law medical officer seems to me to be, at present, the most hardly treated, the least appreciated, and the most depressed. Take, first, the remuneration. You are unfortunately only too well acquainted with the miserable pittances of £50, £80, or £100 a year that the nation allows to thousands of fully qualified practitioners, for laborious duties of the highest importance to the public health, *at a rate which often works out at a few pence per attendance*. Consider the degradation of having to balance the cost of the drugs that ought to be used in any particular case against the prospect of having to spend on that case out of your own pocket far more than you are paid for it. Then consider the total absence of any professional stimulus, the lack of any encouragement by competent inspection, the absence of professional records, the complete indifference of boards of guardians and the Local Government Board to any results, as shown by their failure to ask for any reports or to inquire whether the patients live or whether they die. Finally, think of the future of a Poor-law medical officer. Year after year he may go on in the same round of uncomfortable Poor-law practice, without prospect of promotion, usually without even an advance of salary, without the slightest chance of rising out of the narrow rut into which Fate has thrust him. Has any mark of distinction or any sort of public honour—I do not say a baronetcy, but anything whatsoever—ever been given to a Poor-law medical officer, as a Poor-law medical officer, even for the most meritorious, the most zealous, the most useful, and the most prolonged official service?

In the course of my membership of the Poor-law Commission there was nothing with which I was more impressed than with the amount of devoted work, really quite unpaid for, that the Poor-law medical officers were, as a class, giving to the poor; or than the utter lack of official appreciation and encouragement which that work secured. What many members of the Poor-law medical service feel most is not the miserable pay that they get, nor the lack of official appreciation or encouragement, nor even the absence of honour and dignities, but the extraordinarily narrow scope that, under the necessary limitations of the Poor-law, they find for useful work. It is not encouraging, for instance, to have through one's hands (as the Poor-law medical officer does) one-third of all the deaths from phthisis; and yet, as several Poor-law doctors told us, never to have seen among them a single curable case. It breaks the spirit of a man who cares anything about his professional work to have to go on year after year merely pretending to deal with cases, which have come to him only when destitution has set in, and therefore usually too late for any permanently remedial treatment, under structural and other conditions which he knows will prevent cure, but which he, as a mere Poor-law doctor, has no power to prevent. Meanwhile, he sees the medical officer of health in go-ahead districts advancing from point to point, starting this and that promising experiment, with municipal hospitals, bacteriological laboratories, Roentgen ray treatment, milk dispensaries, school clinics, and what not, obtaining not only all the honour and glory, but apparently unlimited scope, at the public expense, for really useful service of the State.

Now the two Reports of the Poor-law Commission agree in recommending the prompt and complete *destruction* of the present Poor-law system, the abolition of the workhouse, and the abandonment of the well-known "principles of 1834." But they differ vitally in what they propose to construct. The Majority Report proposes that the Poor-law medical service shall continue in England and Wales separate from the public health service, under a separate local authority, and that it shall remain rigidly restricted to attendance on paupers. It follows (as is inevitable under any Poor-law authority) that the patients are not to be eligible even for medical treatment until they have become destitute, and, that the treatment must cease as soon as they cease to be destitute. Moreover, it is proposed that there should be, alongside the work of the Poor-law doctor, a great extension of the contract practice of provident dispensaries, in which as many people as possible are to be enrolled. The fees from these enlarged provident dispensaries are, however, not to be secured to the Poor-law medical officer; they are to be shared among all the doctors of the district, including any newcomers who may be attracted by this bait, according to the number of patients who honour them with their patronage—for everyone, even the pauper, is to have free choice of doctors. The district medical officer will thus find his professional work dwindling, for the competition will be increased, and it will often not be the "parish doctor" who is preferred; and the chance of any improvement in salaries will therefore not be great. Indeed, it is expressly contemplated in the Majority Report that the new Public Assistance Authority will find the duties of the district medical officer gradually dwindling away, his work being more and more taken from him, so that, after more or less lingering, he will be, without abolition of office and therefore without compensation, wholly got rid of.

---

[1] A paper read at the annual meeting of the Poor-law Medical Officers' Association of England and Wales, held at the Guildhall, London, on July 6th, 1909.

The Minority Report proposes, on the other hand, that both the Poor-law medical service and the public health service should be merged in a new county medical service, working under the supervision of an enlarged health committee of the county or county borough council. Into that county medical service would come all the different branches of medical practice that are or may be maintained at the public expense—the isolation and other public hospitals, including the existing workhouse sick wards and the Poor-law infirmaries; the domiciliary or dispensary work of the district medical officer; the whole public supervision of, and whatever public provision is or may eventually be made for, maternity and infancy up to school age; the county homes for the aged needing institutional care, and whatever county institutions may be provided for the crippled and the incapacitated; the milk clinics, the bacteriological laboratories, and the elementary and public secondary school inspection and doctoring; the examination of candidates, the certification and the medical treatment required by all the public services in the county; and the general sanitation of the whole district. Only by some such unification into a county medical service, it is suggested, can we put a stop to the very serious overlapping and duplication between the different rate-supported medical services that is now so rapidly increasing. Only by some such unification can we prevent the Poor-law medical service from being more and more definitely restricted in the scope of its work, and from being more and more overshadowed by the growing public health department.

It is, I think, clear that under such a county medical service, which sooner or later is bound to come, there will be no question of all the work being done by one medical officer. There will be needed all sorts of medical practitioners. To say nothing of the subordinate staff of minor health officers and nurses which would be organised under medical supervision to the extent required by the circumstances of each part of the county, there would be the domiciliary and dispensary practice which the community is bound to maintain for those who cannot pay a remunerative fee to the private practitioner. This would doubtless remain in the hands of the present district medical officers until the occurrence of vacancies permitted a re-arrangement of districts. There would be no disturbance of the rights or positions of existing officers. Probably as the existing district medical officers retire, or to the extent that they may choose to exchange their private practice for a salary and the prospect of a pension, the future will see the private practitioner relieved of all necessity for taking on the laborious and underpaid Poor-law work (like other contract practice) *merely in order to keep out interlopers*. We may contemplate the district medical officer of the future as invariably a whole-timer, absolutely debarred from private practice, properly salaried and pensionable, and provided with a county motor-car to enable him to cover a large district whenever he is summoned by telephone by the local nurses, dispensary attendants, and minor health officers whom the county employs, leaving the private practitioner of the future free to monopolise all the paying practice. Alongside this domiciliary and dispensary service of the district medical officer there would be an institutional branch of the county medical service (into which the district medical officers would be promoted) of medical superintendents and resident medical officers of the various kinds of public hospitals, convalescent homes, phthisis sanatoriums, homes for the aged, institutions for the incapacitated, and what not, into which the present Poor-law and public health institutions of the county would be differentiated. This branch, of course, would be in the main—though not to the exclusion of consulting physicians and surgeons—a whole-time service, recruited largely from the district medical officers of all the counties, debarred from private practice, with adequate salaries and pensions. Alongside these two branches of the county medical service there would be a third, the special sanitary service, probably not localised, but visiting the various parts of the county as required, using the greater mobility now afforded by the motor-car, and discharging such of the duties of the medical officer of health as were not combined with the domiciliary practice of the district medical officer.

Finally, there would be at the head of all, in general charge of the whole medical staff and medical institutions of the county, the county medical officer, probably aided, in the larger counties, by one or more assistants serving, so to speak, on his staff, and representing, probably, different branches of the county medical service. The county medical officer, who would hold a very highly paid and responsible post, and his assistants, who would likewise be whole-timers of lifelong experience, would, in fact, be chosen indiscriminately from any of the three branches of the county medical service, the chance of promotion to the highest posts being thus open to any medical men, whether district medical officers or institution superintendents, clinicians or sanitarians, who developed not only professional but also administrative ability. For it is a great mistake to suppose that the county medical officer need be, or ought always to be, a sanitarian. At present, it is true, the medical officer of health with his D.P.H. is apt to get all the plums, but this is just because the Poor-law medical service is kept outside *as* a separate Poor-law service, in which there is no possibility of advancement. I see no hope of improvement so long as this isolation continues. But the sanitarian has, from the standpoint of county administration, often grave defects. From his lack of experience he sometimes forgets to allow for the difficulties of domiciliary practice. He is apt to leave out of account the very stubborn feelings and prepossessions of the average man, who will not be dragooned into health. He runs the risk of falling behind in his professional knowledge, so far as clinical work is concerned. On the other hand, there are growing up in the Poor-law medical service many men who join high professional qualifications and great range of experience with administrative training as the superintendents of Poor-law infirmaries larger than most voluntary hospitals; or as conducting domiciliary and dispensary practices of greater range and extent than the majority of those who are only private practitioners; or as the resident medical officers of workhouses of gigantic size, in which they have to deal with every age, from infancy to senility, and with every possible case, from childbirth to cancer, from tubercle to typhus.

I venture to think that the part played by the Poor-law medical service in the future county medical service will be one of dignity and importance, and that the early creation of such a unified service, as advocated in the Minority Report, offers the only practical means of putting an end to the very unsatisfactory position in which all sections of the Poor-law medical service now find themselves.

RUSSIAN CONGRESS ON THE BLIND.—At the second Russian Congress on the Blind, which was opened on June 2nd, Mr. M. I. Reich said in a paper "On the Causes of Blindness in Russia," that in European Russia the number of blind is greater than in the remaining governments of Europe, it being 20 per 10,000 of the population. Over 20 per cent. of the blindness was caused through glaucoma and 19 per cent. through trachoma, which proportion compared with other countries is very striking. Other causes were small-pox and suppurating inflammation of the eye in new-born children. He held 45 per cent. of the cases to be preventable and mentioned vaccination against small-pox as one of the most important preventive measures.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.

Plea for a Rational Puerperium.—Minute Anatomy of the Pregnant Tube.

A MEETING of this society was held on July 14th, Professor W. STEPHENSON (Aberdeen), the President, being in the chair.

Dr. F. W. N. **HAULTAIN** read a paper on a Plea for a Rational Puerperium, a record of 100 cases. He had for years thought that the conduct of the puerperium had simulated more that of the convalescence from a severe illness than the management of the sequel of a normal function. After reading von Alvensleben's paper he felt he had some foundation to go upon against popular prejudice and fashion. The mode of management adopted was as follows. The puerpera, if willing, was encouraged to sit up in bed to meals on the second day. As early as she felt inclined thereafter she was allowed to leave her bed and walk to the fireside, where she sat for an hour; on the following day this was repeated morning and evening. The next day two hours morning and evening were spent out of bed, the patient sitting and walking a little if she so desired. The fifth day after rising was practically spent out of bed with the exception of a few hours' rest in the afternoon, and on the tenth day the patient left the hospital. 100 cases followed this line of treatment, all of whom sat up in bed on the second day, 40 rose on the third day, 35 on the fourth, and 25 on the fifth day. Of the 100 cases 47 were primiparæ and 53 multiparæ. Each was carefully examined before leaving the hospital and as many as possible six weeks later. The morbidity in these cases—i.e., a temperature over 100° F. or a pulse over 90 for 12 consecutive hours—was represented by three cases; two developed infective temperatures on the third day, one left the hospital on the sixteenth day, and the other on the twenty-eighth day. Routine examination on the day of leaving the hospital showed the pelvic organs to be normal except in two cases where a slight retroversion of the uterus was present. In one there was considerable varicosity of the legs, but the woman remarked it was not nearly so bad as after previous confinements. All the cases examined six or more weeks after (43 cases) showed involution to be thorough and the position of the uterus normal except in the two cases previously mentioned. The women were uniformly eulogistic in their commendation of the treatment, and the multiparæ having the opportunity of comparison gave it most convincing approval. Was there any advantage to be gained by this radical change in the treatment of the puerperium? Most women after their confinement had during a normal puerperium a feeling of well-being, and it did seem hard to condemn them to ten days or even three weeks of absolute confinement to bed; it savoured rather of punishment for becoming pregnant than of reward for replenishing the earth. Labour was not a disease; the puerperium could not be considered a convalescence; it was merely a natural return of the parts connected with pregnancy to their normal condition, in which was mainly concerned the involution of the uterus and the readjustment of the pelvi-abdominal circulation. Involution was influenced probably by the circulation and was mainly directed by a nervous mechanism which was chiefly sympathetic in nature. The pelvi-abdominal circulation was mostly affected after labour by intra-abdominal pressure and in the fall of pressure after labour the veins were much distended. Exercise of the abdominal muscles would improve their tone, accelerate the abdominal circulation, and diminish constipation. The pathological complications might be classed under four heads: septic inflammation, uterine displacements, subinvolution, and venous derangements. Septic inflammation could not be caused by the position of the patient; but if it had occurred then more free only be effected slightly by the position and it was reasonable to suppose that the improved abdominal circulation would act in a salutary manner. Uterine displacements were affected by position, as when lying on the back the weight of the uterus must stretch the round ligaments and predispose to retroversion. The erect posture tended, on the other hand, to accentuate the normal forward inclination of the fundus by pressing it downwards on the pubes. Venous derangements, especially of phlebitis and embolism, were dreaded as a result of early rising, these occurring mostly after the tenth day. The blood of a puerperal woman was highly fibrinous and to prevent coagulation the circulation should be stimulated. This was most readily done by muscular exertion, by the use of abdominal and leg muscles, which would reduce the dilatation of the veins and improve the sluggish circulation. Maintenance of rest for ten days led to general muscular atony and debility; by rising on the third day there was little loss of general muscular power and constipation was strikingly diminished. It was difficult to understand why women should have been condemned for thousands of years to so much enforced idleness. In primitive races it did not exist. It seemed to have resulted from the religious practice of the ordeal of purification.

Dr. J. **HAIG FERGUSON** said he was not quite convinced by the very plausible arguments in the paper. In America it was found that there was deterioration of the white women compared with the squaws; these latter would fall out on the march, give birth to a child, and resume march on the same day. The white women had more sense. The native women suffered more from displacements and grew old very soon. He agreed with the principles in the paper to a certain extent. He considered the chief use of the binder was to fix the loose joints in the pelvis after labour.

Dr. A. H. F. **BARBOUR** considered the paper of general interest and revolutionary. The subject was introduced by Küstner 11 years ago, giving the results of 1000 cases, but was dropped, and it had again been brought forward within the last two years, the principles being applied both to the puerperal patient and to treatment after operations. Such treatment helped the general condition, the patient acquired more confidence, took her food better, and thus improved. But the local results were not so satisfactory. It was not proved that involution was favoured nor that the lochia were improved, and the question of backward displacement was very important. In the most recent paper 16 out of 46 had a retroversion or retroflexion afterwards. One must remember that if they were even up eight hours, still they were resting the other 16 hours in bed. Three classes of patients must be considered in this question. First, the labouring class in the Maternity; such treatment was the best thing for them, because they could be watched in the ward; it was more pleasant and comfortable for them. A second class was the working woman in her own house; it was best to keep her in bed to prevent her doing house-work. The third class of better patients, who in the development of civilisation were certainly not primitive, were best kept in bed for rest and to keep them out of the interests of life.

Dr. J. **LAMOND LACKIE** could endorse practically all that Dr. Haultain mentioned in his paper, having assisted at the Maternity during the same period. All the multiparæ declared themselves much better than in their previous labours. The treatment was not carried out in severe forceps or abnormal cases, only in simple ordinary cases or easy forceps, but even cases with a slight tear were allowed up. He found great difficulty in introducing this treatment into private practice, the greatest obstructionist being the nurse, as her term of service would be curtailed.

Dr. J. W. **BALLANTYNE** believed it would introduce a new element of danger in a ward, as a patient might thus spread infection if she had any about her. Küstner's paper 11 years ago was buried by Olshausen's disparaging criticism.
M [illegible]
l.. [illegible]
F [illegible]
d [illegible]
claim diminished risk of embolism. Wagener and Gellhorn quoted their experience of Javanese women, who were compelled by a custom to rise for a short time on the first day and move about the house, that among these women prolapse was exceedingly common and embolism frequent. Dr.

Ballantyne believed in a modified adaptation of the treatment.

Dr. W. FORDYCE considered that the results could not be estimated after 10 days. He did not consider Dr. Haultain's physics of the pelvis correct in the production of prolapse. The paper was too severe on the moderate conduct of the puerperium.

Dr. D. E. DICKSON (Lochgelly) said he practised among a population of hard-working women. There were two classes, one which looked upon their confinement as their annual ten days' holiday, and the other class who grudged a few days from their household duties and who usually got up on the third day and did a little household work, and did it all on the tenth day. The results of all these cases were good, as out of 1200 cases he had few displacements or bad sequelæ.

Dr. HAULTAIN, in reply, said there was no hustling with these patients; he asked them first if they wished to get up, both in maternity and private practice. He had examined 43 cases after six weeks and found two displacements. He believed quick rising favoured involution. He had written to medical men at work among the natives of Central Africa, India, and America, and had obtained favourable answers as to this practice among these women. He found that it was usually the mother of the puerpera who objected, not the patient herself.

Dr. JAMES YOUNG gave a lantern demonstration on the Minute Anatomy of the Pregnant Tube, as illustrated by five cases. In one case of a two months' gestation the ovum had developed in the posterior wall of the tube, the anterior wall not being involved, and the fimbriæ were retracted; there was well-marked decidual formation in the tubal folds throughout the entire length of the tube. In another case the ovum was surrounded by a blood mole; this blood was entirely extra-chorionic and contained only a few fœtal blood cells The villi were degenerated but where their tips projected into fluid blood they were well nourished, showing the parasitic nature of the villi and throwing light on the possibility of growth of the placenta after the death of the fœtus. The retraction of the tubal fimbriæ was explained by an over-riding of the mucous and inner coat of muscle over the rest of the tube wall, leading to a withdrawal of the fimbriæ within the tube lumen.

Reviews and Notices of Books.

The Making of Species. By DOUGLAS DEWAR, B.A. Cantab., F.Z.S.; and FRANK FINN, B.A. Oxon., F.Z.S., M.B.O.U. With 15 illustrations. London: John Lane; New York: John Lane Company. 1909. Pp. 400. Price 7*s.* 6*d.*

THIS is a very interesting book, and we may start by recommending the reading of it to medical men as an excellent way of making themselves familiar with the modern position of biology. It is simply and clearly written, the material is well arranged, and the illustrations, which are quite good, also display the points which they are intended to illustrate—a thing which does not invariably occur in popular books of science. For although Mr. Douglas Dewar and Mr. Frank Finn have written a book which shows them to be not only tried and successful zoologists but close students of the best scientific literature, their joint work falls under the title of popular. It is not a book to which Professor De Vries, Professor Bateson, Mr. Frank Darwin, Mr. Karl Pearson, Mr. Frank Beddard, and other leaders of biological science will go for light and leading; it is rather a book which explains the tenets of the various schools of biology, the theories put forward by the leaders of those schools, and the work which has been done or which has been attempted by those who are supporting one or other theory. We have here definitions—which in all their details may not quite be acquiesced in by the different persons whose work is thus categorised—of the Darwinians, Lamarckians, the Neo-Darwinians, the Neo-Lamarckians, the Wallaceites, and the Mendelians. The salient doctrines of these schools are fairly set out, and the places where the particular schemes of biological thought can be found either to explain or to leave unexplained the phenomena of natural history are indicated in plain language, and even a little aggressively. But the attitude adopted by the authors is consistent throughout and justified by the last sentence of the book, which is as follows: "The future of biology is largely in the hands of the practical breeder." For that is the message which they mean to convey.

Mr. Dewar, an Indian civil servant, has already shown himself in his writings to be an authority on ornithology, while Mr. Frank Finn, whose work has also lain largely in the realms of ornithology, has held a position in the Natural History Museum of Calcutta. It is natural, therefore, that a good many of their personal observations should deal with tropical birds, and throughout the book many of the examples given of inheritance, colouration, and the signs and symptoms of variation and hybridism are drawn from bird life. We think it possible that, although the authors are obviously close students of biology generally, they have not given the same attention to the work of the Mendelians—albeit this work is distinctly in support of the practical breeder—that they have given to the life-history of birds. The value and importance of Mendelism may, as they suggest, have been exaggerated, but it is rash to set limits to work the scope of which is increasing almost daily. But the net result of the book is to suggest that natural selection has been worked too hard, especially by Mr. A. R. Wallace, who has attempted to explain too much under this head, and, like his immediate followers, has not given sufficient credit to other possible factors in the creation of new species. In this connexion a happy comparison is made of natural selection to a competitive examination in which it is suggested that natural selection, while tending to diminish the number of species which might arise from mutation by weeding out many mutants, does not of itself make new species, which rather originate in accordance with the laws of variation. "Variation brings into being mutants, which are incipient species, but variation cannot determine their survival. It is at this stage that natural selection steps in But because natural selection allows certain mutations to persist, it is not correct to say that natural selection has caused these mutations or made or originated the species to which they give rise." Upon this view it follows that, in the authors' opinion, while natural selection counts for much, and while its influence on mutations should be frequently capable of simple explanation, we are still far from any real knowledge of evolution as a whole. It is necessary that we should know much more of the causes of variation and mutation than we know yet. To the observation and experiments of the practical breeder the authors combine to look for progress in this direction, and we think that they will find more men of science than they appear to imagine holding the same view as themselves, but certainly with one addition—namely, that the results of biological chemistry must be brought more into line with evolutionary research than is the case as yet.

A great deal of the ground in this book appears to have been covered by Professor Arthur Thomson in his excellent work "Heredity." The authors, whose reference to the labours of other writers is very full and generous, constantly refer to Professor Thomson's manual.

By What Authority? The Principles in Common and at Issue in the Reports of the Poor-law Commission. By JOHN H. MUIRHEAD, LL.D., Professor of Philosophy at the University of Birmingham. With an Introduction by Sir OLIVER LODGE, LL.D., F.R.S. London: P. S. King and Son. 1909. Pp. 90. Price 2*s.* net.

THIS is a reprint of a series of articles in the *Birmingham Daily Post*, written just after the issue of the Report.

The intellectual position of the author is sufficient guarantee of the value of the thought and the quality of the form, while additional force is afforded by the fact that Professor Ashley, one of the highest authorities on economics in the English-speaking world, has revised the proofs and made various alterations in the text. The articles do not deal with the whole contents of the Report, and they avowedly leave untouched the question of medical aid with which our readers are now familiar. Practically they are limited to the economic aspects of the Report, and especially to that part which deals with the question of unemployment, which Professor Muirhead describes as the kernel of the whole. To this side of the subject these articles form an admirable introduction, which can be commended to the many members of our profession who are seeking to formulate their ideas. The lucidity of Professor Muirhead's style and his detachment from party politics are marked throughout his pages.

In a short introductory chapter, published before the Reports of the Commission appeared, a sketch is given of the object and effects of the "New Poor-law" of 1834. Here the aim was to satisfy the claim of humanity that persons who are unable to support themselves should not be left to starve, but also "to secure that there should be sufficient in the conditions of acceptance of Poor-law assistance to deter unnecessary resort to it." The position of the pauper was to be less pleasant than that of other labourers, however poor. This principle has been persistently assailed by modern social reformers, and is entirely jettisoned by the latest Commissioners. In his consideration of the effects of the "New Poor-law" Professor Muirhead is kinder than most critics, who have recently ascribed a deliberate malignancy to the framers of the Act, as if they had foreseen all its difficulties and shortcomings, and intentionally fostered them. On the contrary, it is claimed here that a considerable part of the admitted amelioration in the condition of the working-classes is due indirectly to the Poor-law: a view with which we are very much in accord.

Both Reports of the recent Commission, it will be remembered, unite in condemning the mixed workhouse. The description of the social life of even the best of these institutions, as depicted in the Minority Report, may be sensational and in certain details open to cavil, but in substance it is unquestionably true. It is doubtful if the attack of the same group of Commissioners on the administration of outdoor relief is of equal validity; their criticisms might be applied in similar terms to the Old Age Pensions. The author, being a Birmingham man, of a city where civic and social organisation is very complete and where conventional methods of administration are not over-regarded, thinks the pictures of outdoor relief and its evils are too dark and that valuable work might still be done under the existing *régime* of the Poor-law by capable administration. His comments here form a thoughtful indictment of the Minority document which postulates the abolition of the present law, and we recommend our readers to make an opportunity for reading his words.

Coming to the chapters on unemployment, we are confronted with the causes of pauperism. Old age is the most important. The principal factors in lowering the age of wage-earning are the speeding up of modern machinery and the effect of trade union regulations. Recent legislation has undoubtedly had a bad effect also. The Minority Report examines this question carefully, and concludes that the tendency on the part of unions and employers to discard elderly workmen is unsound, and the conclusion is supported by Sir George Livesey. Chronic sickness is also an efficient cause of pauperism, and in particular tuberculosis and alcoholism. The remedies for unemployment as analysed by Professor Muirhead are decidedly disappointing, chiefly resolving themselves into the erection of labour bureaux and more stringent control of boy labour. But we are not prepared to take the dark view that such helplessness implies. Recent general improvements in public health, by alleviating the sickness which has just been alluded to as a principal factor in the pauperism due to unemployment, will, we believe, make their influence felt quite soon in a forcible manner.

LIBRARY TABLE.

A Manual of Minor Surgery and Bandaging (Heath), for the Use of House Surgeons, Dressers, and Junior Practitioners. By BILTON POLLARD, F.R.C.S. Eng., Surgeon to University College Hospital. Fourteenth edition. London: J. and A. Churchill. Pp. 488. Price 7*s.* 6*d.* net.—For 50 years fresh editions of "Heath's Minor Surgery and Bandaging" have been published with a regularity which indicates a steady demand and a uniform welcome on the part of generations of house surgeons and dressers. To state that this volume is the fourteenth edition is in itself an appreciative notice sufficient for the reputation of most books. But though the original character of this manual has been maintained, and much of its language comes back to our memory like verses from the classics, yet Mr. Pollard has amplified and modernised the whole text, while Dr. Dudley W. Buxton contributes a carefully written chapter on the administration of anæsthetics. The volume is about double the size of Mr. Heath's original book, and the real difficulty in arranging such a manual so as to reject the non-essential has now become very difficult. That modern methods are represented in its pages is shown by the good accounts of spinal analgesia, and of von Bier's treatment of infective processes of joints and tendon sheaths by artificial hyperæmia. Mr. Pollard might have given a little more space to the details of operations for adenoids considering their numerical importance. A certain lack of order and cohesion in the arrangement of subjects is a heritage from the original edition and is to some extent unavoidable, while an excellent index makes it less important than it might have been. The print and get up are excellent and the price is moderate, for there are over 250 illustrations of good quality. We can confidently advise the modern dresser to invest in "Bilton Pollard's Heath."

Notes from a Knapsack. By GEORGE E. WHERRY, M.A., M.C. Cantab., F.R.C.S. Eng. Cambridge: Bowes and Bowes. 1909. Pp. 312.—This is a collection of desultory papers republished from various sources, including our own columns. One or two of the articles have a surgical basis, but the author obtrudes his profession little, and these might almost with advantage have been omitted. There is a paper on the Oriental Mystery of Tongue Swallowing, but it throws no new light on a very doubtful array of statements. Most of this little volume consists of pleasant gossip, with a strong archæological leaning, describing walks in England and Switzerland. Besides his knapsack, the author carried an observant eye and a mind stored by years of varied reading. Something in the flavour of the writing recalls the English essayists of the early nineteenth century, who were all great walkers; and it is impossible to avoid the thought that walking, for walking's sake, produced mental attributes which are rarer now.

Notes and Thoughts from Practice. By W. J. TYSON, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng., Honorary Physician, Victoria Hospital, Folkestone. London: John Bale, Sons, and Danielsson, Limited. 1909. Pp. 95. Price 2*s.* net.—This little volume is a collection of rambling notes and impressions which scarcely merit the form of a complete volume, though they would have been acceptable in the pages of a magazine. For there is much that is thoughtful and useful in Dr. Tyson's notes, but they are sometimes too familiar. The page on the danger of putting old people to bed is excellent for example, but surely the danger is well recognised. "Some Thoughts on Cases resembling Typhoid Fever" are suggestive, but they might with advantage go further afield and raise distinctions between true enteric fever and paratyphoid fever, and between ptomaine intoxications and bacillary cultivations in the intestine. "Foreign bodies in the eye are very common in Folkestone," says Dr. Tyson so, we believe, they are in all other towns. Such accidents are peculiarly common in the centres of engineering where steel lathes and other machine tools are employed, but surely not in Folkestone. Dr. Tyson quarrels with the ophthalmic teaching at our medical schools, and claims that it is too minute and specialised, and deals too much with the rarer conditions of the eye to the exclusion of the commoner ones. But it must be remembered that the teaching of ophthalmology, like other forms of teaching, is, or should be, an education, and that a student who is carefully taught to recognise the features of a rare or obscure eye condition is in a position to recognise a common or simple one; moreover, the failure to recognise dangerous and rare conditions of the eye causes more disaster to patients than do errors in any other department of medicine. Among the most interesting parts of the book are the remarks on appendicitis, the plea for the extension of local anæsthetics, and the notes on pneumonia and the soporific action of mercury.

Hernia: Its Etiology, Symptoms, and Treatment. By W. McAdam Eccles, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to, and Demonstrator of Operative Surgery at, St. Bartholomew's Hospital, &c. Third Edition. London: Baillière, Tindall, and Cox. 1908.—This edition differs but little from earlier issues, and it is only necessary to say that it is the best practical book on the diagnosis and treatment of hernia suitable for the general practitioner. Many students when they pass their final examinations know all about the rare varieties of hernia, and the various methods of radical cure, but they are often unable to adjust a truss or to advise whether a truss should be employed or an operation be performed. This is exactly the book that will enable them, when in practice, to make up these deficiencies. The author almost apologises in his preface for saying so much about the non-operative treatment of hernia, but this is the very part of the treatment that is most required in text-books intended for those in general practice.

McQueen's Private Account Book. Arranged for one year's use, may be commenced at any time. For Country or City Gentlemen. Leicester: J. McQueen and Co. Price 10*s.*, post paid.—Medical men are generally not good men of business, and much of this is due to their want of knowledge of the method of keeping accurate accounts. Many of them manage more or less satisfactorily to keep the accounts of the practice, but private accounts are of almost equal importance if a practitioner is to know where he stands financially. This account-book should prove of real advantage to medical men, for it is admirably arranged, so that it is possible to see at any moment the exact financial position. The records for income discriminate between that from the profession, that from dividends, and that from other sources, and the expenditure is also divided up into several sections, such as household, servants, subscriptions, and professional payments. For every month there is a summary and a record of the condition of the bank account. A useful section is that of professional profit and loss account and income-tax statement. We commend the book to the notice of our readers.

The Annual Charities Register and Digest. 1909. London: Longmans, Green, and Co., and the Charity Organisation Society. Pp. cccliv.–696. Price 5*s.*——*The Year Book of the Scientific and Learned Societies of Great Britain and Ireland.* London: Charles Griffin and Co. Pp. 352. Price 7*s.* 6*d.*——*The Public Schools Year Book.* London: Swan Sonnenschein and Co. Pp. 717. Price 3*s.* 6*d.*——*The Girls' School Year Book.* Same publishers. Pp. 594. Price 2*s.* 6*d.* net.——*The Englishwoman's Year Book.* London: A. and C. Black. Pp. 372. Price 2*s.* 6*d.* net.—To review or summarise year books is impossible, and the best thing we can do is to refer our readers who may require trustworthy information upon the charities, or the learned societies, or the public schools, or the occupations open to women in the United Kingdom to the pages of one or other of the books themselves. In the first of these volumes Mr. C. S. Loch's introduction on "How to Help Cases of Distress" is, as he claims, a reference book in itself, and not the least convenient part of it is the legal information concerning the Poor-law which it includes. The motto of Mr. Loch's society might almost be taken from the opening paragraph of one of the sections of this introduction. "Generally speaking, the test of the usefulness of charitable institutions is, whether or not they produce self-help in the recipients of their bounties and in the people at large." There follow a series of 16 articles on special branches of charitable work, of which Dr. T. N. Kelynack contributes two on the Arrest of Tuberculosis and the Care and Control of the Inebriate, whilst Dr. H. Rayner writes on Lunatics, Idiots, and Imbeciles. A review of the past year's charitable work is then given, followed by an account of the Charity Organisation Society, the rest of a bulky volume being made up of summarised information returned by all classes of reputable charities, which are classified according to their respective objects. In the main care and discrimination have been exercised in the choice of the institutions to be mentioned, and the eighteenth edition of the work will be found indispensable to all interested in the palliation and reform of many social evils.—Of the other books before us *The Year Book of the Scientific and Learned Societies of Great Britain and Ireland* contains a record of the work done by those bodies during the session 1907–08, including lists of papers reported in their proceedings and information concerning their objects and officials. The book is complete enough to include the medical societies attached to the various metropolitan and provincial hospitals.—*The Public Schools Year Book* contains particulars of the arrangements and teaching staffs of nearly 120 schools administered by governing bodies and forms a trustworthy guide for parents able and desirous to do the best by their sons. We note that it has been adopted as the official reference book of the Headmasters' Conference.—*The Girls' School Year Book* is a companion volume dealing in a like manner with the secondary education of girls in this country.—*The Englishwoman's Year Book* is a compendium of information dealing with all the activities of the woman of to-day, advising her on the choice of a profession or occupation, giving her information on the educational facilities at her disposal, and on the laws, the charities, and the institutions especially concerned in her interests. In discussing the profession of medicine for women the remarks of Dr. May Thorne on Medical Women and their Prospects at a conference held last year are quoted. They strike us as a fair statement of the position, although perhaps not very encouraging for the medical woman of average ability and without capital or influence. The same section includes a list of women practitioners of medicine.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B.; ALEXANDER MACALISTER, University of Cambridge; ARTHUR THOMSON, University of Oxford; ARTHUR KEITH, Royal College of Surgeons of England; and in this number by the late D. J. CUNNINGHAM, University of Edinburgh. Vol. XLIII., Third Series, Vol. IV., Part 4, July, 1909. London: Charles Griffin and Company. Annual subscription, 21*s*.—The contents of this number are: 1. The Topography and Morphology of the Human Hyoid, by F. G. Parsons, F.R.C.S. Eng. Amongst other features the author describes a curved bar on the anterior surface of the body joining the two lesser cornua and apparently corresponding to the basal part of the second visceral arch, and observes that the chondroglossus is a constant muscle and that the inferior lingualis does not arise from the hyoid; that the lesser cornua do not ossify until the fourteenth year, and never form synovial joints with the body of the hyoid, though they often do so with the greater cornua. The article is illustrated with eight drawings in the text. 2. The Arrangement of the Papillary Ridges on the Human Hand and Foot, by Walter Kidd, M.D. Lond., F.R.S.E., F.Z.S., with three illustrations in the text. 3. Abnormal Position of the Heart and Great Blood-vessels, associated with Transposition of the Viscera, by Adrian Stokes, B.A. Trinity College, Dublin, with three figures in the text. 4. A Note on a Large Intra-abdominal Pelvic Colon and on the Etiology of Peritoneal Adhesions, by Douglas G. Reid, M.B. Edin., demonstrator of anatomy in the University of Cambridge (Trinity College). 5. Note on an Anomalous Anastomosis between the Internal Carotid and Basilar Arteries, by G. Elliot Smith, M.A. Cantab., M.D. Syd., F.R.S., Cairo, with a figure in the text. 6. A Gland upon the Ear-conch of Dasyurus Maugei, by R. H. Burne, M.A., assistant conservator, Royal College of Surgeons of England, with three drawings in the text. 7. A Contribution to the Development of the Prostate in Man, by Evelyn John Evatt, University College, Cardiff, with eight illustrations. 8. Two Abnormal Sterna in Living Subjects, by Professor A. M. Paterson, Liverpool, with two figures in the text. 9. A case of Abnormal Right Subclavian Artery, by E. L. Pearce Gould, B.A., with three figures in the text. 10. A Contribution to the Histology of the Human Osseous and Membranous Labyrinth, by Sidney Scott, M.S. Lond., F.R.C.S. Eng., with 21 highly creditable illustrations. 11. A Liver exhibiting Multiple Anomalies, by E. Barclay-Smith, M.D. Cantab., with an illustration. Lastly, there are two Anatomical Notes, one by Mr. N. Bishop Harman, on Spectacles for Fine Dissections, and one on a case of Hernia of the Adipose Capsule of the Kidney, by D. G. Reid, M.B. Edin. The number contains in addition the Index of Vol. LXIII., the Title, and Table of Contents.

Heart: A Journal for the Study of the Circulation. Edited by THOMAS LEWIS, M.D. Lond. Vol. I., No. 1. London: Shaw and Sons. 1909. Subscription price per volume 20*s*., single numbers 5*s*. 6*d*. each.—We have already published an annotation welcoming the appearance of this the first number of *Heart*, giving brief notices of the papers contained in it, and referring to the prefatory note contributed by Dr. W. H. Gaskell and to the editorial preface. The papers contained in this number are: 1. The Irregularities of the Mammalian Heart observed under Aconitine and on Electrical Stimulation, by Arthur R. Cushny. An interesting analysis of the various irregularities induced by aconitine is given. These comprise reversal of the rhythm, a condition in which the impulse to contraction is generated in the ventricle and spreads up to the auricle; irregularities from impairment of conduction in the auriculo-ventricular bundle leading to partial or complete block in either direction—viz., from auricle to ventricle or *vice versâ* in reversed rhythm; alternation in strength of the contractions; extra-systoles in auricle or ventricle, sometimes occurring at regular intervals and producing the condition of "continuous bigeminus" described by Hering; and sudden changes in the rhythm of the whole heart. These effects are attributed to the aconitine retarding the recuperation of the contractile and conductive power, while it increases the tendency to spontaneous movement—i.e., it increases irritability. Some irregularities induced by electrical stimulation of unpoisoned hearts are also described. 2. Nodal Bradycardia, by James Mackenzie. From a study of the venous pulse Dr. Mackenzie has demonstrated a disturbance of the cardiac rhythm in which the auricle no longer contracts at its normal place in the cardiac cycle. He has brought forward evidence that the stimulus to contraction originates in these cases in a situation other than the normal, and he suggests that this may be the node from which the auriculo-ventricular bundle runs. He has therefore termed this condition "nodal rhythm." In most cases the nodal rhythm is associated with an increased rate of beat, but in this paper a condition of bradycardia is described which is believed to be related to the nodal rhythm and which is differentiated from heart block. Dr. Mackenzie gives illustrative cases, in some of which epileptic manifestations occurred. 3. Paroxysmal Tachycardia, by Thomas Lewis. An interesting study of this obscure condition is given, with detailed instrumental records of one case and descriptions of others. Two forms are differentiated, one an auricular form in which the sequence of contraction in the chambers is normal, and the other in which the auricle does not contract at its usual position in the cycle. In the auricular form, with which Dr. Lewis chiefly deals, the rhythm of the paroxysm is described as being *sui generis* and differing from that in the intervals between the paroxysms. Although extra-systoles may occur in this form they are not regarded as the basis of the paroxysm. Evidence is brought forward which tends to show that the paroxysm is due to intrinsic changes within the heart rather than to disturbed central innervation. A ventricular form of paroxysmal tachycardia can be produced in animals by ligation of the right coronary artery. 4. The Measurement of the Systolic Blood Pressure in Man, by Leonard Hill, with the cooperation of Martin Flack and W. W. Holtzmann. This paper contains a record of further work concerning the vexed question as to whether the rigidity of the arterial wall may be a source of error in observations made by instruments of the Riva Rocci and Hill and Barnard type. Dr. Hill concludes that there is no evidence that the resistance of the arterial wall to compression affects the systolic index of blood pressure, but he finds that the relative softness or hardness of the arterial walls affects the "conductance" of the systolic wave markedly and so modifies the readings. The arm and leg readings are the same in young men when quiet and in the horizontal posture. The arm and leg readings differ after the violent exercise of stair-climbing and in aortic cases. A difference between arm and leg readings is most marked in all cases of aortic regurgitation, and when such patients are lying quiet in bed this difference is a diagnostic sign of aortic regurgitation.

The Bio-chemical Journal. Edited by BENJAMIN MOORE, M.A., D.Sc., and EDWARD WHITLEY, M.A. Vol. IV., Nos. 3, 4, 5, 6, and 7. April 26th and July 2nd, 1909., Liverpool: Johnston Laboratories. Price 15*s*. per volume of 480 pages. —These numbers of the *Bio-chemical Journal* contain several articles of importance, amongst which we may notice that of Dr. E. W. Wace Carlier of Birmingham on allyl isothiocyanate, which he shows exerts in the rabbit a powerful depressor effect on both the heart and the respiration very quickly after administration, the inspiratory efforts exceeding the expiratory, the effect with moderate doses soon passing off. This drug cannot be recommended for internal use. Dr. W. Webster of Manitoba treats of choline, and finds that none can be detected in normal blood and does not regard its presence in minute quantity in the cerebro-spinal fluid as indicative of degenerative changes in the nervous system. Dr. Karl H. van Norman of Toronto discusses the value of the biuret reaction in the recognition of protein, and points out that to obtain satisfactory results the solutions of albumin, copper sulphate, and sodium should be of definite strength, the best being albumin in distilled water 0·2 per cent., sodium hydrate 10 grammes to 100 cubic centimetres of water, and copper sulphate 5 grammes to 100 cubic centimetres of water. The limits of delicacy with both the biuret reaction and with cold nitric acid are given. Dr. Benjamin Moore, the Johnston Professor of Biochemistry in the University of Liverpool, and Mr. Edward Whitley, contribute an article on the properties and classification of the oxidising enzymes and analogies between enzymic activity and the effects of immune bodies and complements—a long and carefully drawn up article giving the results of many experiments. Dr. Hugh MacLean, Carnegie Research Fellow, of Aberdeen, gives an account of a mon-amino-diphosphatide lecithin-like body in egg yolk, and also gives the results of his investigation of the nitrogen-containing radicle of lecithin and other phosphatides. Dr. A. C. Hof, Höchst a. Main, states that iodo-eosin is a test for free alkali in dried-up plant tissues. Dr. Benjamin Moore and Dr. R. Stenhouse Williams describe the growth of the bacillus tuberculosis and other micro-organisms in different percentages of oxygen. Mr. A. E. Jessup, Mr. A. C. Jessup, Mr. E. C. C. Baly, F.R.S., Dr. F. W. Goodbody, and Mr. E. Prideaux contribute a joint article on the electrical forces of mitosis and the origin of cancer. G. C. Mathison, Sharpey scholar, contrasts the several methods of estimating the amount of phosphorus in urine, preferring Neumann's method as modified by Plimmer and Bayliss. Mr. R. A. Robertson, Dr. James Colquhoun Irvine, D.Sc., and Miss Mildred E. Dobson, Carnegie scholar, contribute jointly an article on the polarimetric study of the sucroclastic enzymes in Beta Vulgaris. Dr. Ernest E. Glynn of Liverpool University and Mr. G. Lissant Cox supply some observations upon possible errors in the opsonic index.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) MERCURETTES; (2) ADRENALIN PREPARATIONS; AND (3) PITUITRIN.

(PARKE, DAVIS AND CO., BEAK-STREET, REGENT STREET, LONDON, W.)

1. Mercurettes offer a very convenient form to the physician for administering mercury by inunction. They consist of oblong blocks each containing 30 grains of very finely divided mercury incorporated with 60 grains of cocoa butter. Cocoa butter appears to be well adapted for the purpose as it is free from objectionable odour, its consistence is convenient, and it rarely becomes rancid. 2. Amongst new adrenalin preparations may be noted tablets containing 1-200th grain of the hæmostatic. It is said that a prompt physiological effect is obtained when one or more of the tablets are placed under the tongue, the drug being rapidly absorbed in that area. Tablets are also prepared containing adrenalin with the anæsthetic novocaine, a combination of obvious value in certain surgical operations. Again, adrenalin is combined with chloretone in a suppository, the result being a medicament possessing constringent, analgesic, and antiseptic properties which render the suppository valuable in rectal disorders. Another suppository contains, besides adrenalin, three grains of formidin (an iodine, salicylic acid, and formaldehyde compound), three-quarters of a grain of cocaine hydrochloride, and three grains of extract of hamamelis. The formula is an excellent one, having regard to the effectual germicide (formidin) present, the analgesic (cocaine), and the tonic astringent (hamamelis). 3. The extract of the pituitary gland behaves like adrenalin, but its vaso-motor constrictor action is more prolonged, while its influence on the circulatory system is similar to that of digitalis and strophanthus. The dose of pituitrin orally or hypodermically is from 10 to 30 minims four times daily.

DIAMALT EXTRACT WITH COD LIVER OIL

(THE BRITISH DIAMALT COMPANY, 11 AND 13, SOUTHWARK-STREET, LONDON, S.E.)

We have already remarked upon the high diastasic value of this company's malt extract. According to our experiments diamalt digests nearly seven times its weight of starch at body temperature and as much as 13 times its weight of starch at higher temperatures. It is therefore not surprising that diamalt blends perfectly with a high percentage of cod-liver oil. Samples recently submitted to us yielded respectively 17·00 and 33·73 per cent. by weight of cod-liver oil. The excellence of the malt extract adds not a little to the palatability of the compound in spite of the oil. Altogether these preparations may be regarded as the standard of a malt and cod-liver oil combination.

ANTISEPTIFORM No. 2.

(CORBYN, STACEY, AND CO., LIMITED, BRUNTON'S WHARF, 673, COMMERCIAL-ROAD EAST, LONDON, E.)

Antiseptiform No. 2 affords an ingenious and convenient method of obtaining formaldehyde gas for the purpose of disinfection. It consists of a mass of soap saturated with methyl alcohol, and at ordinary temperatures the mixture is solid. On applying a light to the mixture contained in a tin the alcohol ignites. Next, a disc of platinised asbestos gauze is held over the flame until hot, and then pressed down upon it. The flame is extinguished and the vapours are acted upon by the spongy platinum—that is to say, a continuous current of formaldehyde gas is given off by the partial oxidation of the methyl alcohol. According to a bacteriological report before us the method can be effectually applied to the disinfection of rooms.

SOLOID PRODUCTS FOR IONIC MEDICATION.

(MESSRS. BURROUGHS, WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

We have received examples of soloid products which are convenient for the application of drugs by cataphoresis, or, to use the modern expression, ionic medication. Each soloid when dissolved in a fluid ounce of water gives a 1 per cent solution of the drug—that is to say, each product contains 4·37 grains of the drug. Amongst the ionic soloids submitted to us were sodium chloride, zinc sulphate, and potassium iodide, but others are prepared. The ionic soloid offers the important advantage of presenting a drug in a pure state, judging from the results of our examination.

RHINOCULIN CREAM.

(SCHACHT WARNER AND CO., 55, FORE STREET, LONDON, E.C.)

Any preparation which is calculated to relieve the distressing disorder known as hay fever would be welcomed by a number of sufferers. Such a property is claimed for rhinoculin cream, which is prepared after the formula of a physician in Germany. The favourable results which are recorded of its use in hay fever appear to be due first to the selection of a pure fatty basis which provides against the penetration of pollen into the mucous membrane and, secondly, to the employment of a non-poisonous local anæsthetic.

GLIDINE PREPARATIONS

(MENLEY AND JAMES, LIMITED, MENLEY HOUSE, FARRINGDON ROAD, LONDON, E.C.)

We have already referred in these columns to glidine, which is an interesting vegetable protein food resembling, as we pointed out, the gluten of wheat flour. We also mentioned a compound of glidine with iodine which suggested a means of administering iodine with advantage over the ordinary iodides. We have now received further glidine compounds containing the elements bromine, iron, mercury, and arsenic, known respectively as bromoglidine, ferroglidine, luesan, and arsan. According to some literature before us these somewhat remarkable preparations deserve attention, inasmuch as glidine appears to offer an excellent and effective way of administering the various elements indicated. The fact that these elements have been combined with such an innocent substance as wheat gluten is alone important.

PURE RECTIFIED SPIRIT

(THE POLISH POTATO GROWERS' AND DISTILLERS' ASSOCIATION AND THE WARSAW RECTIFYING COMPANY. REPRESENTATIVE FOR THE UNITED KINGDOM, J. JANASZ, 9, PERCY ROAD, BOSCOMBE, HANTS)

We have not examined a purer specimen of ethyl alcohol than the one prepared by the above commercial associations It is well known that alcohol obtained from potato starch by careful fermentation, distillation, and rectification yields the best results as regards purity and palatability. Alcohol derived from sugar and grain invariably contains traces of impurities which give a pronounced and often objectionable character to the taste. Beet spirit, in fact, has been known to contain a base of the nature of an alkaloid. It appears that in Poland the production of grain spirit cannot compete with that of potato spirit owing to the latter being considerably cheaper to distil in that country than the former. According to our analysis the spirit is not far off being absolute alcohol. The actual figures obtained were: alcohol, by weight 95·57 per cent., by volume 97·20 per cent. On examining the spirit for the common *impurities of ordinary spirit practically nothing of the kind* was found. It contained the merest trace of aldehyde, absolutely no furfural, and no higher alcohols of which amylic alcohol or fusel oil is the type. The absence of any odour or flavour apart from that of pure alcohol is remarkable, and the product is what distillers call an exceedingly "clean" spirit. In these circumstances the adaptability of such a pure spirit for medicinal and pharmaceutical purposes must be conceded. For analytical and research work also no purer alcohol can be obtained.

HYGEIA MINERAL WATER.

(THE ILKLEY BREWERY AND AERATED WATER CO., LIMITED, ILKLEY.)

This water is marked by its peculiarly palatable quality, it is fresh to the taste. According to our analysis it exhibits an alkalinity equal to about five grains of bicarbonate of soda per pint. It contains, however, besides bicarbonate of soda, the bicarbonates of the alkaline earths, magnesia and lime. Organically the water is pure.

COCOA AND CHOCOLATE.

(THE MAZAWATTEE TEA COMPANY, LIMITED, TOWER HILL, LONDON, E.C.)

Two specimens of cocoa were examined and the results showed a reduction in the amount of fat consistent with the digestibility of the products, while there was no evidence of the presence of added alkali. The total fat in the cocoa essence amounted to 33·00 per cent. and in the cocoa to 34·5 per cent. The mineral matter in the former was 5·70 per cent. and in the latter 5·50 per cent., while the alkalinity of the ash calculated as potash (K_2O) was 3·60 per cent. and 3·70 per cent. respectively. These results, coupled with the excellent flavour of the infusion, indicate the selection of a cocoa of high quality and the adoption of satisfactory methods of manufacture. Amongst the samples sent to us were also milk chocolate and some creams, both again evidencing the use of high grade cocoa in their preparation.

ENGLISH CREAM.

(H. FRANCIS AND SON, 11, ARTHUR STREET WEST, LONDON BRIDGE, E.C.)

The cream was contained in an air-tight tin, and on opening was found to be in a sound condition and uniform in quality. Considering that the cream had been sterilised the flavour was very satisfactory and approaching that of ordinary fresh cream. Analysis gave the following results: moisture, 63·75 per cent.; fat, 30·29 per cent.; curd and sugar, 5·58 per cent.; and mineral matter, 0·38 per cent. In the cream, which is a thick cream, we could find no foreign substances present.

Looking Back.

FROM

THE LANCET, *SATURDAY*, July 30th, 1831.

DUTY ON FOREIGN BOOKS.

To the Editor of THE LANCET.

SIR,—I have read with much pleasure in a late number of the *Westminster Review*, that the French government has proposed to that of England, a mutual exchange of all literary works of merit which may appear in each country. It must be admitted that this is a liberal proposal; but it would be a much more generous policy to remove *in toto* the tax on foreign books. The medical profession is not the only one that would derive considerable advantage from such a measure; and if our government would abandon this onerous duty, it would facilitate very much the opportunities for procuring the best continental authors, and thereby contribute to what has been sneeringly but not inaptly called "the march of intellect" This tax upon knowledge affords but a paltry addition to the revenue, but it is yet extremely exorbitant when levied upon private individuals. A few weeks ago I returned from the continent, and brought with me several foreign books, a certain duty upon which I was of course prepared to expect; but when passing them through the Custom House, I was obliged to pay the extravagant tax of a shilling *per pound* It is true that I had but seven shillings to pay, although I had several pounds weight more of foreign books, but I owed my escape either to the indifference or to the indulgence of the man who searched my trunks. He took out a French work on Hygiene, and an Italian one on medical jurisprudence, with two or three other small ones, and these altogether weighing seven pounds I was called on to pay seven shillings, which enhanced the original price of those books very much.

The plan of weighing is certainly a very ludicrous and barbarous mode of estimating the value of literature; *for* the more ponderous a book is, the more valuable and productive it is in the eyes of the Board of Customs. These censors never look at the *esprit* which a work contains, but at the quantity of paper or material in it; and the weight, but not the wit [illegible] its utility.

This [illegible] made the length [illegible] his wisdom and intelligence

By publishing the above you will afford a useful piece of information to those English students who are now on the continent, and who think, as I did, that they will have but threepence per pound to pay on the importation of foreign publications.

I am, Sir, yours, &c.,

VIATOR.

July 21, 1831.

THE LANCET.

LONDON: SATURDAY, JULY 31, 1909.

The British Medical Association: The Presidential Address.

THE address delivered by Sir WILLIAM WHITLA at Belfast in his capacity as President of the British Medical Association, although it dealt incidentally with many men and things of local interest and importance, was yet in the main a careful and serious pronouncement upon questions of high public and professional significance in relation to the conduct of medical education. Sir WILLIAM WHITLA, in the researches which culminated last year in his Cavendish lecture on the Etiology of Tuberculosis, has given ample evidence of his abundant power to grasp the scientific aspects of a popular question, and hence, when he turns away from the histories of bygone worthies, or from the claims to consideration of the city and the university which he adorns by his presence and guides by his example, in order to address himself to the changes in the conduct of medical education which are called for by the progress of knowledge, he is entering upon a path in which he possesses unanswerable claims to be accepted as a guide. When he tells us that the first duty of every medical school or faculty is the establishment of a radical reform in the now accepted curriculum, under which "the brain of the student fails to expand in assimilative power with the growth of advancing science," he formulates an indictment of existing methods to which those who are now engaged in applying or in supporting them will certainly be required by public opinion to plead. When, also, he tells us that a considerable proportion of medical students, either after failing to pass in the preliminary subjects of physics, biology, and chemistry, or before presenting themselves to the examiners in anatomy and physiology, proceed to attend classes in advanced subjects, and to go into the wards with the earlier examinations still hanging over their heads, we can hardly dispute his conclusion that such a course of procedure must "paralyse their capacities for obtaining anything like an efficient training in the subjects whose practice is to become their ultimate life work." He declares, indeed, that "after more than a quarter of a century's experience as a hospital teacher and as an examiner, embracing a practical acquaintance with the working of three universities in the United Kingdom," he feels constrained to believe that, in respect of sending out men qualified immediately to enter upon the routine practice of their profession, we are, in some respects at least, behind the results obtainable in the old days of apprenticeship. Such a belief will not appear unreasonable if we remember the testimony borne by many great men, and conspicuously by Sir JAMES PAGET, with regard to the practical benefits which a well-guided system of apprenticeship was calculated to confer upon the pupils, more especially in the way of preparing them to engage usefully in the daily work of the profession, even though existing circumstances make a return to the system of apprenticeship well-nigh impossible.

If we compare the educational requirements of the present day with those of previous centuries or generations, we shall perhaps find reason to hope that the collective intellectual capacities of the human race are being gradually trained in the direction of an increasing competence to deal with the many new problems presented to them. Exceptional individuals may perhaps be disregarded, for they have arisen at all periods of history and have seldom been fully appreciated by their contemporaries. They supply standards to which it is conceivable that mankind may ultimately attain, but which have no immediate bearing upon practical questions. We discuss contemporary dramatists without comparing them with SHAKESPEARE, and contemporary physicists without comparing them with NEWTON. But we may justly compare the beginning of the twentieth century with the beginning of the eighteenth, and if we do so we shall hardly fail to observe evidences of progress which afford just ground for hopefulness concerning the future. The intellectual culture of QUEEN ANNE's day was mainly through the elegant inaccuracies of the "humanities," and "exact" knowledge scarcely existed, save in the custody of a few geometricians. It was possible, of course, to verify a quotation; but "certainty" in the scientific sense of the word could scarcely be predicated of anything that was described as "learning," and close reasoning upon secure data was practically confined to the observatories of astronomers. There is no reason to suppose that the wits of the period, however brilliant, would have been capable of the minute examination of phenomena and of the sound judgments concerning causation which are daily accomplished by the men of science of our own time. In all probability the brain cells of the average man of education were deficient in directions in which they have since undergone some increase of development, and if this be so it is not unreasonable to assume that the educational methods which were sufficient for our ancestors are no longer calculated to produce the best attainable results in the cases of our descendants. The men of the present day, and of the days soon to follow, will be increasingly called upon to subdue the physical forces of nature to the service of their kind, and the mental faculties required for this purpose are of a different order, and must be called into activity in a different way, from those which would be concerned in furnishing a trope for Hudibras, or an appropriate classical quotation for a common room. It is true universally that "reading maketh a full man; conference a ready man; and writing an exact man;" but the qualities so described will be exercised about questions which were known to BACON, if at all, only through the inspiration of genius; and the faculties subordinate to them must now be developed in the manner best calculated to enable them to grapple with the new problems which all new knowledge is certain to bring in its train. The education of medical students should be systematically so directed as not only to supply them with the knowledge which they will be required to apply to purposes of practical utility, but also so as to train the faculties of their minds in the directions most favourable to the forms of mental activity hereafter to be required from them. Precise scientific information, valuable or even invaluable as it must always be, is yet inferior in importance to the cultivation of the judgment in relation to the authenticity of statements, and in relation to the true nature and characters of phenomena.

The measure of reform suggested by Sir WILLIAM WHITLA is set forth at length in his address, and will demand the careful attention alike of the medical corporations and of the General Medical Council. He proposes to anticipate the hoped-for arrival of better science teaching in public schools by a "radical change in the method of teaching the entire group of preliminary and scientific subjects," and by a complete devotion of the later period of the curriculum to clinical work. An important report on science teaching in public schools has lately been drawn up by the science master to the Charterhouse, and has been issued in pamphlet form by the Board of Education; but it cannot be said to afford any substantial grounds for hope that the schools themselves will take any active part in the institution of necessary reforms, or will move in the matter otherwise than slowly, and under an amount of pressure from public opinion which has not yet been applied to them. The report is based upon the replies to a circular of inquiries framed by the author in conjunction with the officials of the Board of Education, and it is significant that, while only one of the schools applied to sent a definite refusal to afford the desired information, quite a large proportion of them left courteous inquiries from a Government department wholly unanswered, and were presumably unable to answer them in a satisfactory manner. In the case of another profession in which the proficiency of its members is a matter of imperial concern, and in which, as in that of medicine, such proficiency is largely dependent upon training in the principles of scientific thought and judgment, as well as upon an acquaintance with scientific facts and methods, in the case, that is, of the Royal Navy, it has been found imperatively necessary that the future officer should be caught young, and that his training, from the first moment when he begins to specialise, should be conducted on lines completely in harmony with the duties of his future calling. We confess to a great doubt whether more than a small proportion of the medical students of to-day have been so trained, before entering upon their special studies, as to bring to them minds which have assimilated the first principles of scientific teaching, and are prepared to the full extent of their several capacities to judge wisely of the relations between phenomena. If this be so, the task of the teachers of medicine and surgery is rendered unduly difficult by the imperfect receptivity of their pupils, and some at least of these pupils, if or when they ultimately make their way through the meshes of examinations, are practically certain to have much to learn at the bedside, and are at least likely, in the course of the process, to exemplify the maxim of political economy which teaches that all learners spoil a portion of the raw material which passes through their hands. We may yet see the establishment of an institution having for its object to give the instruction necessary as a preliminary to hospital studies, and bearing to the medical profession something of the relation which the College at Osborne bears to the Royal Navy. The "science teaching" of an ordinary school usually occupies too subordinate a position in the curriculum to form an adequate preparation for lives which should be constantly conducted under scientific guidance.

The British Medical Association: The Address in Medicine.

THE annual meeting of the British Medical Association affords an opportunity for the presentation to large numbers of the medical profession of the results of new investigation and of a review or summing up of the present state of knowledge in the various branches of their science. In particular, the addresses in plenary congress are employed in this double capacity. During recent years the prevention and treatment of tuberculosis have taken a prominent place in scientific discussions, and the problems involved have been constantly brought before the public by means of the provisions proposed or adopted by local authorities in order to try and lessen the incidence of the disease. In his Address in Medicine Dr. R. W. PHILIP touched in a masterly manner on many points in connexion with the outlook of modern medicine on tuberculosis, and the summary which he gave of the forward movement which has taken place during the last 35 years is full of interest, and forms a useful introduction to the larger views on immunisation and the more advanced methods of therapeutics now being practised. He very properly pointed out that the physician and the sanitarian had joined hands, and had been aided not a little by educated social workers who recognised the vast part played by tuberculosis as an agent of national devitalisation and impoverishment. The report of the Registrar-General indicates the great fall in the number of deaths from this disease that has occurred during the last 50 years, the decline being mainly due, no doubt, to the improvement in sanitary matters that has been effected. It is only by a hearty and thorough coöperation on the part of the medical profession, their patients, and the public at large that any further diminution in the mortality from tuberculosis can be accomplished.

The natural way to attempt to stamp out a disease is, of course, to discover its cause and the manner in which it is spread, and then to take such steps as may best prevent these etiological factors from taking effect. Unfortunately, the dissemination of tuberculosis is too complicated a matter for easy prevention. Dr. PHILIP, however, drew attention to one feature in tuberculosis the importance of which in regard to etiology and prophylaxis cannot be exaggerated—namely, the frequency of tuberculous infection in childhood. The reason for this tendency has not yet been clearly determined. As in the adult, there are probably several causes at work, the two principal ones being the introduction of the pathogenic bacilli by respiration and the ingestion of food contaminated by the bacilli. The former for many years has been considered the main danger, and, as a consequence, the greatest care is now taken in the disposal of the sputum from patients suffering from pulmonary tuberculosis, and certain laws have been enacted, which we trust are being duly enforced, to prevent indiscriminate spitting in public places and conveyances. Recently, however, infection by the milk and flesh of tuberculous animals has claimed much attention, the former especially being blamed not only for the occurrence of the disease in young life but also for its appearance in later life, the germs of the disease having in the meantime remained latent. Dr. Philip raised certain well-founded objections to this view, one of the strongest being the fact that tuberculosis flourishes abundantly in not a few countries where feeding with milk from cows or other animals appears unknown. But he referred to another factor in the dissemination of tuberculosis the removal of which would, we believe, have as much effect in the prevention of the disease in childhood as any measure that could be introduced. The condition to which we refer is the relatively airless conditions of home and school life, especially amongst the poorer classes. He pointed out that the ratio of increase of pulmonary tuberculosis is greater about the time the child goes to school; also that one morbid influence seems constant throughout the progressive stages of the child's life—namely, the comparative withdrawal of the developing organism from the natural and healthful stimulus of the open air. These undesirable conditions do not only exist in the large towns. Those of our readers who have visited some of the villages in the Highlands of Scotland, or the small communities on the Devonshire or Cornwall coasts the inhabitants of which mainly obtain their living by fishing, may have noticed the anæmic, even unhealthy appearance of many of the children. Closer observation will show the large number of cases in which there are enlarged glands in the neck, or the scars marking the former presence of such glands. This condition may in part be due to improper feeding, but if the houses in which the children are brought up be visited the close and tainted atmosphere in which they sleep and spend a large portion of their time will at once suggest the most potent cause of their debilitated condition. Such homes may be indeed veritable "nests" of tuberculosis. Legislation directed to the removal of such houses would do as much to benefit the health of the community as the destruction of the slums in the large towns.

Dr. Philip proceeded at some length to consider the great principle of aerotherapy. He maintained that the application of this method of treatment had completely changed the clinical features of pulmonary tuberculosis, and even went so far as to observe that the classic type of disease as described from generation to generation in the past has ceased to be. Whilst not being able to corroborate Dr. Philip in such an advanced statement, we cordially support him in his contention that aerotherapy is the most satisfactory measure yet introduced for the treatment of certain types of cases, and even that it may be successful occasionally in apparently hopeless conditions. The best results, however, are obtained when the patients are able to indulge in graduated exercise and labour, a phase of aerotherapy which Dr. Philip does not refer to. Finally, he discussed tuberculin and vaccine-therapy and spoke in an encouraging tone of the results which he had obtained by the use of tuberculin, but he has not yet convinced himself of the value of controlling the administration of the remedy by means of the opsonic index. There is now ample evidence to prove that the value of tuberculin treatment was too hastily condemned shortly after it was first introduced in 1890. Many observers have since published their results, and all these hold out a promise of good to come, but the actual value of tuberculin and the most satisfactory method of its administration require further investigation. We have found Dr. Philip's remarks most interesting and suggestive. In discussing a subject of supreme importance to humanity in general he has drawn proper attention to the merits and defects of modern views, and this is the way to enable the medical profession to realise the results obtained and the problems which still remain for inquiry and elucidation.

The British Medical Association: The Address in Surgery.

It was a happy idea to select Mr. A. E. Barker to deliver the Address in Surgery at Belfast, for he comes from the north of Ireland and is, indeed, a Fellow of the Royal College of Surgeons in Ireland as well as of the English College. Mr. Barker has devoted much attention to the surgery of the abdomen and also to local and spinal anæsthesia, and these formed the main subjects of the address. When antiseptic surgery was first introduced its more enthusiastic supporters were inclined to over-estimate the value of the application of antiseptic substances, and at the same time to under-estimate the protective powers of the body against the assaults of micro-organisms. As Mr. Barker has pointed out, when surgeons first ventured to attack the contents of the abdominal cavity they were imbued with the idea that the peritoneum was one of the most vulnerable tissues of the body, but gradually it came to be recognised that it possessed wonderful powers of repair. This had been seen by some before the introduction of the practice of antiseptic surgery, but when the new principles were understood the powers of repair possessed by the peritoneum were for a time forgotten, and the successes obtained were ascribed entirely to the virtues of the antiseptics employed and the general cleanliness practised in the operation. Before long, however, the conviction was forced on the mind of the surgeon that as many cases of abdominal surgery had recovered before the days of antiseptics absolute asepsis of the peritoneal cavity could not be essential, because a certain amount of infective substance must have been sometimes left behind in the abdominal cavity without serious or fatal result, showing that the peritoneum must have been able at first to tolerate and later to remove completely the dangerous material. The more the pathology of intra-abdominal sepsis was studied the more clear it became that the powers possessed by the peritoneum of disposing of septic organisms must be very great, for otherwise no case of acute appendicitis, for instance, could possibly recover, and yet it was certain that many such cases did recover even without surgical interference. The natural deduction from these facts was that the peritoneum was not the enemy of the surgeon but his ally, always willing to assist him in dealing with septic organisms, a deduction which raised doubt whether it was desirable to use germicides freely within the abdominal cavity, for they might by damaging the peritoneum interfere with its inherent reparative powers.

Time has intensified our appreciation of the ability of the peritoneum to deal with a bacterial invasion; bacteriology and biology have furnished us with some explanations of the clinical facts, and at present we know something definite about the defensive powers of the peritoneum. The effusion of plastic lymph for the repair of a lesion or for the shutting off of an infected area is only a part of the capabilities of the peritoneum. We know now that under irritation it can pour out an abundant fluid, which dilutes the toxins present, and, moreover, that this fluid, like healthy serum, has the property of inhibiting or destroying bacterial growth. This power is not unlimited, and it not rarely happens that the bacterial invasion, either from its quantity or its quality, may overcome the protective forces of the peritoneum, but every year our opinion of the powers of defence possessed by the peritoneum is being enhanced, and we may learn some effective way of evoking these powers to the full. The practice of increasing the amount of blood and serum in a damaged part by means of poultices and fomentations is of great antiquity, but the biological mechanism by which hyperæmia acts in arresting septic processes has only recently received close study, and now we do not fear so much as formerly the hyperæmia of and effusion into serous cavities. Under the influence of BIER'S views on hyperæmia we increase intentionally the amount of blood and the effusion of serum in some affected areas, and we obtain the very best results. It has been conclusively shown that joint cavities swarming with certain bacteria may be rendered sterile by the hyperæmic treatment. It seems certain now that inflammatory effusions into the peritoneal cavity, induced by the presence of septic organisms, may be up to a certain point definitely beneficial. We are as careful as, even more careful than, before in preventing the entrance of micro-organisms from without during an abdominal operation, but we are more anxious now to avoid damaging the serous membrane by rough handling, by chemicals, or by the chilling of exposure, while we are much more hopeful and much bolder in practice when sepsis is already present in the abdomen. In proof of this Mr. BARKER quoted certain cases. For example, he operated about a year ago on a boy who had a tuberculous abscess in the left iliac fossa. A collection of fœtid pus was found in the midst of adherent small intestine, and as the finger attempted to separate them the bowel wall gave way. It was necessary to resect a considerable length of small gut in order to obtain healthy bowel for the anastomosis. All this was done without antiseptics in the presence of foul pus, some of which must have been left behind, yet Mr. BARKER thought it better to close the parietal incision without drainage. For some days pus oozed out between the stitches, but the discharge soon ceased and complete recovery followed. In another striking case a woman, 49 years old, had an internal strangulation. The abdomen was opened 20 hours after the onset, the patient being cyanosed and pulseless; fœtid greenish-brown fluid gushed out, and nearly five feet of gangrenous bowel had to be resected. Here, too, the wound of the abdominal wall was closed without drainage and perfect and permanent recovery followed. These cases showed clearly that the peritoneum was able to deal with the septic matter that remained after removal of the damaged bowel and the bulk of the effused fluid. Without a belief in the power of the peritoneum to deal with much septic material a surgeon could only look upon such cases as these as hopeless, and would probably abandon the operation. Any prolonged attempts to clean the peritoneal cavity would not only have been futile, but injurious to the defensive powers of the peritoneum. Mr. BARKER next referred to the fortunate issue of cases of cerebro-spinal meningitis as illustrative of the wonderful protective and reparative functions of the serous membrane enclosing the central nervous system when aided by the injection of antitoxin. The conclusions to be drawn from his words are that other serous membranes as well as the peritoneum have a very great power of dealing with infection, both bacterial and toxic; that it is not difficult to lower this natural protection by injudicious interference with the membrane itself; but that by removing some of the effused material, and by otherwise aiding the serous membrane in its conflict with the invaders, much good can be done.

Another subject dealt with by Mr. BARKER was spinal anæsthesia. He spoke strongly in its favour, and as he has had probably more experience of this method than anyone else in this country his conclusions are of great value. He expressed the opinion that the conditions under which operations are performed with spinal anæsthesia are immeasurably superior to those present when a general anæsthetic is used. There are absolute quiet and relaxation all over the field of operation, and these are of vast importance when delicate parts have to be accurately adjusted. At present surgeons are in a position of doubt as to the true value of this method and probably it is not employed to the extent it deserves, but there is justification for advancing slowly in this direction, as even those least willing to set bounds to the possibilities of surgical achievement must allow. Mr. BARKER is very hopeful of the future of surgery. To those to whom it may appear that we have reached, or almost reached, the bounds of what surgery can accomplish, Mr. BARKER says that what has been achieved is almost as nothing to what remains to be done. Certainly every year shows us new avenues along which progress can go, and though it is impossible and useless to attempt to indicate the exact directions of the further extension of surgery, we agree with Mr. BARKER that we are far indeed from the time when it shall be said that surgery has reached its limits.

Annotations.

"Ne quid nimis."

BRITISH PHARMACEUTICAL CONFERENCE.

AT the annual meeting of the British Pharmaceutical Conference, opened on July 26th at Newcastle-on-Tyne, an interesting departure was made from the practice which has been in vogue since the first meeting of the conference, 46 years ago. This will be seen by a report of the Conference which appears in this issue of THE LANCET. Hitherto, except for the observance of social duties, the work of the conference has been confined to the reading and discussion of papers on subjects relative to the scientific aspect of pharmacy, but on the present occasion a portion of time was set aside for the consideration of problems which, while they are perhaps more capable of understanding by the ordinary pharmacist than most of the scientific papers presented, are of such a character as the founders of the conference would have preferred to leave to some differently constituted body. "Should doctors dispense?" is a question which may be of interest to pharmacists, as is the cognate question, "Should pharmacists prescribe?" "Problems of the Poison Schedule" is a subject admirably adapted to debate, but it is questionable whether the value to be gained from such discussions compensates for the time which might have been devoted to the purpose for which the conference was founded—namely, the advancement of pharmaceutical science. The papers were quite up to the average of previous years, and some of them contained valuable suggestions of a practical character. For instance, prescribers will no doubt welcome the formula suggested for an improved ointment base to replace the unsatisfactory paraffin ointment at present official. The examination of a number of samples of malt extract and cod-liver oil discloses such an unfortunate state of affairs as to make it seem desirable in the interests of the public that some standard should be set up for this important preparation. From an economic point of view the contribution on the use of alcohol in pharmacy is one which should prove useful in the compilation of future editions of the Pharmacopœia. With a tax of 23*s.* per gallon on rectified spirit, apart from other reasons, it is very desirable that only the minimum of alcohol that is scientifically necessary should be used in the preparation of galenical preparations, and in this paper an experienced investigator showed that 24 tinctures could be prepared with alcohol of lower strength than that prescribed officially.

DEMORALISING FACILITIES.

EVERYBODY must recognise the advantages of cheap travelling, and the competition amongst those who undertake to convey the public from place to place is such as to reduce the cost to a minimum. In many cases, indeed, it is stated that the public are practically carried for nothing. The inducement to ride rather than walk is thus a temptation which continually confronts the public. It is not difficult to see in this a process which is calculated to lead to physical, and not improbably mental, demoralisation. If a man can reach his home by tramcar or omnibus for a ½*d.* he is not going to trouble himself about walking the distance. He thus loses, perhaps, daily a valuable and healthful form of exercise because travelling is so cheap. Formerly he walked the distance to save a relatively costly fare. The lift is another example of a modern innovation which encourages idleness, and which, indeed, threatens to make the staircase a superfluous and obsolete channel. This is very strikingly illustrated in a large hotel where the great palatial staircases constructed before the days of lifts are scarcely now ever used. Another example of the demoralising tendency of cheap transit is seen in the travelling platform which is designed to save so much walking. Everywhere machinery is devised to save physical effort as though we possessed no means at all for getting about ourselves. Surely this state of things cannot count for sturdiness and healthful activity in the future generation, but is more likely to lead to a state of atrophy which must react unfavourably on the individual. It is open to question whether the human race is better off for at any rate a number of facilities which are constantly thrown in its way. There are, of course, compensations, but not, we think, in all cases.

THE IDEAL PUBLIC-HOUSE.

THE eighth annual report of the executive committee of the Central Public-house Trust Association dealing with the year ending Dec. 31st, 1908, lies before us and contains matter of considerable interest. The object of the association, it may be remembered, is to promote temperance by the elimination of private profit from the retail sale of liquor and by securing to the public the monopoly value of licences. The report, though officially dealing with the year 1908, is dated June, 1909, and mentions a conference of Public-house Trust companies held in March, 1909, at which sundry main principles were accepted as to how Trust Public-houses should be worked. The chief of these is No. 7 which lays down that "the general arrangement and management of each Trust house shall be on the lines of a house of general refreshment and not of a mere drinking bar." This to our mind is the line along which temperance reform could run with the greatest certainty of securing widespread support from all thoughtful people. The report refers among other matters to certain faults in the licensing laws as illustrated by the conduct of the licensing magistrates in East London, where, although the licensing magistrates said that they thoroughly approved of the Trust system, yet upon a technical point they could not see their way to grant a licence to a particular Trust Company. However, despite difficulties with red tape, the association is doing good work, and we heartily wish its operations that extension which will enable it to carry out its aims in a wider field than is at present possible. Until, however, the intentions of the Government as to legislation are made plain, the directors are wise not to try to extend their business.

SUBLUXATION OF THE NECK.

IN the *Journal of the American Medical Association* of June 5th Dr. F. M. Sherman has reported two cases of subluxation of the neck—a comparatively unrecognised condition. He suggests that it is much more common than is supposed and that many cases which are diagnosed as "stiff neck" or torticollis from cold are examples of it. The position of the head is characteristic. If the articular process of one cervical vertebra is displaced forwards the head will be more or less tilted to the opposite side and may also be rotated towards it. This is the position in subluxation. But if the unilateral dislocation is complete, so that the articular process goes far enough to drop down in front of its fellow, the head will be turned towards the opposite side but tilted towards the same side. It is of interest that in both the cases the condition occurred during sleep and was noticed on awaking, the time when torticollis from cold usually is first observed. In the first case a girl, aged 19 years, awoke suddenly in much pain and unable to turn her head. The condition continued during the remainder of the night and on the following day, when Dr. Sherman was asked to relieve her "stiff neck." The head was tilted to and slightly turned towards the left. The muscles on the right side of the neck were tense. The spinous process of the fourth cervical vertebra was about half an inch out of line with the others. Under ether anæsthesia the method of reduction worked out by Dr. Walton of Boston was performed. The head was bent diagonally backwards and to the left and then rotated into place. At once the condition of the neck changed from rigidity to free mobility. On recovery from the anæsthesia the patient was completely relieved. However, deep tenderness persisted on the right side of the neck for several weeks. In the second case the patient was a young man who during the previous six months had twice had the same trouble in minor degree. On awaking he felt pain and stiffness in the left side of the neck. This grew worse during the following day. On examination the head was decidedly tilted towards the right. The left side of the neck was painful and tender and the muscles were tense. As the previous displacements had been spontaneously reduced Dr. Sherman determined to attempt reduction without anæsthesia. He found it somewhat difficult on account of spasm of the muscles but accomplished it with immediate relief. A stiff collar was applied and worn at night for some time. Some tenderness persisted for a few days. Dr. Sherman thinks that in the great majority of cases of subluxation of the neck the displacement of the articular surfaces is but slight, so that reduction takes place spontaneously.

THE INTERNATIONAL CONGRESS OF MEDICINE.

AT a meeting of the National Committee for Great Britain and Ireland held at the rooms of the Medical Society of London on July 22nd, with Dr. F. W. Pavy, the President, in the chair, it was proposed by Sir William J. Sinclair, seconded by Mr. L. Eliot Creasy, and carried, that the members of the National Committee be circularised as to the advisability of asking His Majesty's Government to invite the Seventeenth International Congress of Medicine to meet in this country. A report was made upon the appointment of official delegates at the Budapest Congress. It was also pointed out that members of the Congress who desire to travel with the party of the Royal Society of Medicine should communicate at once with Mr. J. Y. W. MacAlister at 20, Hanover-square, London, W.

A "SCHOOL CLINIC" FOR BRIGHTON.

THE Brighton education authority at its meeting on July 20th decided to establish a school clinic. When the Act of 1907, imposing upon every local education authority the duty of making provision for the inspection of children, was passed it was quite understood that in the first year or so of its operation little could be done beyond preparing statistical tables of what the school medical officers found. Remedial treatment is the natural corollary, and the education committee at Brighton, acting upon the advice of its medical officer, in conjunction with the medical officer of health, has decided to seek the necessary powers to have delegated to it the authority to provide such treatment in cases where it is required and to debit the ratepayers with the money so expended. But the Brighton proposal is a very modest one. Succinctly stated it is to provide a clinic where the work would be confined to the diagnosis and treatment of contagious skin diseases; to subscribe to hospitals in order to obtain an adequate supply of letters entitling school children to free treatment; and to provide spectacles. The amount to be asked for annually is £100, and it is proposed that of this sum £10 10*s.* should be given to the Sussex County Hospital and £5 5*s.* each to five other hospitals in the town so as to secure letters. Even with a maximum expense of £100 per annum only there was some little objection on the part of some members of the education authority, but they were overruled by another member who reminded the committee that the whole community suffered if the health of the child was bad. We shall watch with interest this step taken by the education authority of Brighton.

TUBERCULOSIS OF THE SUPRARENAL CAPSULES WITHOUT MELANODERMA.

IT is, perhaps, not sufficiently recognised that tuberculosis of the suprarenal capsules may prove fatal without any pigmentation of the skin. The condition, though pathologically similar to Addison's disease, wants the most characteristic feature in the description of that great clinician. It is important that the practitioner should be on his guard as to this possibility, for the diagnosis is easily missed and may be made only at the necropsy. Indeed, here, too, it may be overlooked, for the suprarenal capsules are not organs which receive much attention. Thus the warning given by medical jurists to examine them lest inquisitive questions be asked as to their condition in cross-examination has a very serious basis. At a meeting of the Société Médicale des Hôpitaux of Paris on May 28th M. Ch. Achard and M. Ch. Foix reported the following case. A thin and sickly looking chimney sweep, aged 20 years, was admitted into hospital on Dec. 14th, 1908. His father was dead and the cause of his death was not known. His mother was attending hospital for tuberculous lymphadenitis with suppuration and sinuses. The patient had never seriously been ill. He had ceased work three days before because of fatigue, vomiting, and abdominal pains, principally on the right side. A practitioner who saw him diagnosed influenza. The abdominal pain was not acute and was principally in the epigastrium and right flank; it consisted of attacks of "colic separated by intervals of tenderness." The abdomen was supple and not tympanitic. Pressure on it was a little painful everywhere, and especially in the appendicular region. There was constipation. The temperature was 101·3° F. and the pulse was 90. The face was emaciated and a little drawn; the eyes were a little sunken and surrounded with dark circles. A purgative was given and after a motion the patient improved and the temperature became normal. On the 21st he appeared to have recovered and was discharged. On the 28th he was readmitted because he was always in pain and repeatedly vomited. The face was emaciated and still more drawn. The abdomen was supple but was always the seat of dull pain which predominated on the right side and was increased by pressure. The temperature was normal and the pulse was 80. These symptoms continued until Jan. 5th, when the patient improved and was able to get up. From the 10th to the 14th the vomiting recurred, being sometimes alimentary, sometimes bilious. The patient was always fatigued and constantly felt pain in the right side of the abdomen. On the 15th he died suddenly. The necropsy showed no trace of tuberculosis in the lungs. The liver, spleen, kidneys, and intestines, in particular the appendix, were normal. The suprarenal capsules showed manifest changes. They were hard and easily removed. The right capsule was somewhat enlarged of 1906 with excellent results in syphilis, in daily amounts of 18 grammes, representing 6 grammes, or about 90 grains of metallic mercury. The daily amount should be regulated, according to the susceptibility of the patient, 10, 15, or 20 grammes being rubbed in daily on 30 successive days. The frictions should last about ten minutes, care being taken to rub slowly. Dr. Dupuy prefers to apply the friction at the bend of the limbs or on the inner surfaces of the thighs. It is preferable to abstain from washing the parts for several hours after each friction in order to facilitate the absorption of the mercury. The ease of absorption is shown by the fact that mercury has been found in the urine after applying the friction for five minutes and then washing the skin with soap and water. Although the results obtained with this preparation in syphilis were generally most encouraging, it did not materially relieve the dry, papular eruptions of this disease. Apart from syphilis, the oleobrassidate of mercury has been used with excellent results in parasitic affections of the skin, including pityriasis, which readily yields after two applications, followed by washing with soap and water.

THE Department of Public Health of Queensland in a bulletin dated June 19th states that so far as Brisbane is concerned no case of plague has occurred during the present year. At Mackay a boy, aged 14 years, employed at a boot store and residing at MacAllister-street, died on June 6th. Live filaria worms were found in the blood on the 3rd. Examination of post-mortem specimens revealed the presence of bacillus pestis, but when the health officer and an inspector of this department visited Mackay on June 5th no trace of disease was discovered among a large number of rats examined.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

IN a recent annotation[1] we announced the decision to which the Education Committee of the London County Council has come with regard to the immediate arrangements for the medical treatment of London school children at existing institutions, this decision being based upon the report of the Day Schools Subcommittee. It will be remembered that the consideration of this important matter was begun by the London County Council in July, 1907, when that body appointed a representative subcommittee, consisting partly of its own members and partly of members appointed by medical bodies and other institutions interested in the result to be arrived at, to advise as to whether the systematic medical treatment of London school children (the need for which had been rendered apparent by their medical inspection) should be undertaken by existing institutions or in institutions created *ad hoc*, that is, in special school clinics.

The report of this subcommittee, together with the observations made upon it by the Finance Committee, was presented to, and considered by, the Council during March and April last, and we reported these deliberations and their result in THE LANCET of April 10th, p. 1069. We will repeat the terms of the main recommendations then made to the Council by the Day Schools Subcommittee.

> (*a*) That, as the existing provision of [illegible]ivate and hospital practice sufficiently me[illegible] case of children requiring operative and [illegible]e thus removed from the direct purview [illegible] no further steps be taken in respect of this class.
>
> (*b*) That to supply the additional provision for the medical treatment of school children which has been found desirable, the Council should utilise institutions of the types now existing, giving financial help, if necessary, and receiving special facilities in return for any grant of public money, but that in districts where no suitable institution exists, and where within a reasonable time it shall have been found impossible to make the necessary provision by an extension of existing institutions, the Council should consider whether, in default of other *means*, it shall make the provision itself, and that it be referred to the Education Committee to report further on the matter.

It should be remembered that although the Day Schools Subcommittee had adopted these recommendations upon the report of the Special Subcommittee of 1907 to which we have referred, it transpired subsequently that they represented the opinion of only the minority of that Special Subcommittee, and that its majority report had been strongly in favour of establishing school clinics on the dual grounds of efficiency and economy. On May 1st last the arguments and views expressed in this majority report were circulated amongst the members of the London County Council, and they have been since placed on sale in an official publication. We summarised and discussed these views in our issue for May 8th.

At the meeting of the London County Council on March 30th, when the Day Schools Subcommittee's recommendations came up for discussion, the views of the majority of the Special Subcommittee of 1907 were not, officially at any rate, before the Council, and, as we reported, Mr. Jackson moved the adoption of the second of these recommendations but was defeated by an amendment of Mr. Hayes Fisher, who moved—

> That notwithstanding the declaration of the Prime Minister on March 18th that the Council cannot expect to receive any increased grants from Imperial funds towards the cost of medical treatment of children in the London schools, this Council, being of opinion that certain of the diseases referred to in the foregoing reports are of such a nature as to justify their medical treatment by the education authorities, refers the recommendation back to the committee to report as to the estimated cost of the treatment of each of these diseases, as to the degree to which they affect the educational efficiency of the schools, as to the steps which should be taken to give effect to this resolution, and also as to the steps to be taken to secure such an amendment of the Education (Administrative Provisions) Act, 1907, as will enable local educational authorities to recover the costs of such treatment from parents who are in a position to pay for it.

This amendment having been carried as a substantive motion, the recommendation was referred back to the Day Schools Subcommittee, which reported on May 19th that it was prosecuting inquiries in respect of eye, ear, and skin ailments, but had postponed for six months the question of the consideration of teeth. The publicity which was given to the proceedings of the Council gave rise to a considerable amount of discussion amongst the medical staffs of the metropolitan hospitals as to the advice which they should offer to the managing boards of their respective institutions with regard to accepting the responsibility of treating large numbers of the London County Council's school children, and we were able to place before our readers a representative body of medical opinion upon an admittedly difficult subject. At the same time we gave our own views on this important matter in a leading article,[2] whilst fully recognising the latitude of opinion which must necessarily prevail in a situation where the interests of the school children, the hospitals, the private medical practitioners of the Council's school area, and of the ratepayers are all concerned, and to some extent are at cross purposes.

From what we have said it will appear that the Council has been engaged for the past two years in deliberations of a somewhat complex character, but we trust that we have made clear the position in which the labours of its Education Committee, that body's Day Schools Subcommittee, and the Special Subcommittee of 1907, with its majority and minority reports (the second of which has alone been officially debated by the Council), have at present resulted, that is, in the reference back to the Day Schools Subcommittee of recommendation (*b*) printed above in the light of the instructions contained in the Council's resolution of March 30th. The latest result of this reference has been the preliminary report which this subcommittee presented to the Education Committee of the Council at the meeting of July 14th in view of the approaching long vacation of the Council and of the urgent need of treatment for children suffering from diseases of the eye, ear, and skin, although the inquiries with regard to their treatment have not yet been completed. The report first rehearses nine points suggested to the Education Committee in a memorandum from the Finance Committee as necessary to be considered in connexion with any scheme which the Education Committee may recommend, and proceeds as follows:—

> The inquiry which has been so far conducted has been directed towards ascertaining (1) the number of children affected; and (2) what

the hospitals would be prepared to do in the way of treatment. With [illegible]

ringworm, 3014; total, 43,746.

With regard to the hospitals, we caused a letter to be sent to 56 hospitals which deal with eye, ear, and skin ailments, explaining the [illegible]

[illegible] These may be divided [illegible] desire to coöperate with [illegible] athy and are anxious to [illegible] present accommodation, [illegible] ory may be placed four [illegible]

[illegible] t a grant of [illegible] nent to the [illegible] ction by the [illegible]

[illegible] to coöperate [illegible] specifically stated that they can take more cases per week. In this category there may be placed at present six hospitals. There is reason to believe that as time goes on the number of hospitals in this category [illegible]

[illegible]

It has been intimated by certain hospitals that if they undertake [illegible]

We recommend—

(a) That the offers of the authorities of the undermentioned hospitals to provide medical treatment, free of charge, for school [illegible] almic [illegible] apel- [illegible] reen, [illegible] Royal [illegible] rand, [illegible] and [illegible] d to [illegible] solution (a).

(c) That arrangements be made to secure medical treatment of [illegible] ordinary means, for a payment not exceeding £50 a year for each additional medical assistant (working one half day a week) required to be engaged for the treatment of such children, together with a sum of 2s. for each child so treated to cover the other expenses incurred by the hospitals; and with, if necessary, (ii.) the authorities of other hospitals who may be prepared to undertake such treatment on similar terms; and that the Education Committee do submit a report upon the results of such negotiations in due course; and that the Council be recommended accordingly.

A statement is appended to the report analysing the replies received from the various hospitals in tabular form, of which the following is a brief summary:—

[illegible]

[illegible] ous to coöperate so [illegible] unable to accept [illegible] London Hospital [illegible] Hospital, Italian [illegible] perance Hospital, [illegible] and St. Thomas's Hospital.

3. Hospitals willing to coöperate and to take additional cases: Central London Ophthalmic Hospital, Hospital for Sick Children (Great [illegible] Queen's [illegible] hthalmic [illegible]

[illegible] oöperate [illegible] present, [illegible] Charlton Cottage [illegible] (Dalston-lane), [illegible] Diseases of the [illegible] Throat (Golden- [illegible] spital for Acci- [illegible] Hospital (Soho), [illegible] es of the Skin [illegible] ases (Holborn), [illegible] London Hospital [illegible] al (Marylebone-road).

The table summarises the information received from the above-mentioned hospitals under the following heads: 1. Number of cases at present taken of children of school age. (The replies furnished on this point were meagre.) 2. Number of additional cases which could be taken. 3. Details as to payment required. 4. Other details embodied in the replies.

There was a considerable diversity in the answers received under these headings. Perhaps the most enterprising was from St. John's Hospital for Skin Diseases, which offered to treat the estimated 3000 ringworm cases in the Council's schools in the course of one year for £1000, undertaking the full responsibility of bringing each case to a conclusion, an offer which has not commended itself to the Education Committee. As an example of the number of additional cases which can be taken, Charing Cross Hospital will undertake 1000 refraction cases, 300 to 350 skin cases, and 1000 throat and ear cases a year; whilst the London Hospital is willing to treat 15 aural and 15 ophthalmic cases on four days a week and 20 skin cases on two days a week. The Great Northern Hospital estimates that it can deal with about 3700 new cases a year, allowing for four hours' work per week of one ophthalmic and one aural assistant, and for treating 200 ringworm cases. The Central London Ophthalmic Hospital can take 120 extra cases a week. The Queen's Hospital for Children, Hackney-road, will take 400 refraction cases, 2500 discharging ear cases, and 900 ringworm cases annually; and the Royal Westminster Ophthalmic Hospital will take 60 new cases a week, to 25 of the Victoria Hospital for Children, Chelsea. It will be noticed that the last named of these hospitals are those whose offers of treatment the Education Committee are prepared to accept, as stated in their first recommendation to the Council. We note that St. George's Hospital, in its reply, expressed its anxiety not to interfere with the work of the general practitioner, and we cannot doubt that the committees of other hospitals took this important point into consideration before framing their replies

The recommendations (a) (b) (c) (d) embodied in this report were adopted by the Education Committee on July 14th, after a discussion in which Mr. A. J. Shepheard, Dr. Beaton, and Mr. W. Sanders declared themselves in of 1906 with excellent results in syphilis, in daily amounts of 18 grammes, representing 6 grammes, or about 90 grains of metallic mercury. The daily amount should be regulated, according to the susceptibility of the patient, 10, 15, or 20 grammes being rubbed in daily on 30 successive days. The frictions should last about ten minutes, care being taken to rub slowly. Dr. Dupuy prefers to apply the friction at the bend of the limbs or on the inner surfaces of the thighs. It is preferable to abstain from washing the parts for several hours after each friction in order to facilitate the absorption of the mercury. The ease of absorption is shown by the fact that mercury has been found in the urine after applying the friction for five minutes and then washing the skin with soap and water. Although the results obtained with this preparation in syphilis were generally most encouraging, it did not materially relieve the dry, papular eruptions of this disease. Apart from syphilis, the oleo-brassidate of mercury has been used with excellent results in parasitic affections of the skin, including pityriasis, which readily yields after two applications, followed by washing with soap and water.

THE Department of Public Health of Queensland in a bulletin dated June 19th states that so far as Brisbane is concerned no case of plague has occurred during the present year. At Mackay a boy, aged 14 years, employed at a boot store and residing at MacAllister-street, died on June 6th. Live filaria worms were found in the blood on the 3rd. Examination of post-mortem specimens revealed the presence of bacillus pestis, but when the health officer and an inspector of this department visited Mackay on June 5th no trace of disease was discovered among a large number of rats examined.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

IN a recent annotation[1] we announced the decision to which the Education Committee of the London County Council has come with regard to the immediate arrangements for the medical treatment of London school children at existing institutions, this decision being based upon the report of the Day Schools Subcommittee. It will be remembered that the consideration of this important matter was begun by the London County Council in July, 1907, when that body appointed a representative subcommittee, consisting partly of its own members and partly of members appointed by medical bodies and other institutions interested in the result to be arrived at, to advise as to whether the systematic medical treatment of London school children (the need for which had been rendered apparent by their medical inspection) should be undertaken by existing institutions or in institutions created *ad hoc*, that is, in special school clinics.

The report of this subcommittee, together with th observations made upon it by the Finance Committee, w presented to, and considered by, the Council during Ma and April last, and we reported these deliberations and ' result in THE LANCET of April 10th, p. 1069. We repeat the terms of the main recommendations then m the Council by the Day Schools Subcommittee.

> (*a*) That, as the existing provision of private and hospit sufficiently meets the requirements in the case of childrer operative and in-patient treatment (who are thus remove direct purview of the educational authority), no further st in respect of this class.
>
> (*b*) That to supply the additional provision for the med of school children which has been found desirable, the utilise institutions of the types now existing, giving ' necessary, and receiving special facilities in return for public money, but that in districts where no suitable institutio and where within a reasonable time it shall have been found impo to make the necessary provision by an extension of existing institution the Council should consider whether, in default of other means, it shall make the provision itself, and that it be referred to the Education Committee to report further on the matter.

It should be remembered that although the Day Schools Subcommittee had adopted these recommendations upon the report of the Special Subcommittee of 1907 to which we have referred, it transpired subsequently that they represented the opinion of only the minority of that Special Subcommittee, and that its majority report had been strongly in favour of establishing school clinics on the dual grounds of efficiency and economy. On May 1st last the arguments and views expressed in this majority report were circulated amongst the members of the London County Council, and they have been since placed on sale in an official publication. We summarised and discussed these views in our issue for May 8th.

At the meeting of the London County Council on March 30th, when the Day Schools Subcommittee's recommendations came up for discussion, the views of the majority of the Special Subcommittee of 1907 were not, officially at any rate, before the Council, and, as we reported, Mr. Jackson moved the adoption of the second of these recommendations but was defeated by an amendment of Mr. Hayes Fisher, who moved—

> That notwithstanding the declaration of the Prime Minister on March 18th that the Council cannot expect to receive any increased grants from Imperial funds towards the cost of medical treatment of children in the London schools, this Council, being of opinion that certain of the diseases referred to in the foregoing reports are of such a nature as to justify their medical treatment by the education authorities, refers the recommendation back to the committee to report as to the estimated cost of the treatment of each of these diseases, as to the degree to which they affect the educational efficiency of the schools, as to the steps which should be taken to give effect to this resolution, and also as to the steps to be taken to secure such an amendment of the Education (Administrative Provisions) Act, 1907, as will enable local educational authorities to recover the costs of such treatment from parents who are in a position to pay for it.

This amendment having been carried as a substantive motion, the recommendation was referred back to the Day Schools Subcommittee, which reported on May 19th that it was prosecuting inquiries in respect of eye, ear, and skin ailments, but had postponed for six months the question of the consideration of teeth. The publicity which was given to the proceedings of the Council gave rise to a considerable amount of discussion amongst the medical staffs of the metropolitan hospitals as to the advice which they should offer to the managing boards of their respective institutions with regard to accepting the responsibility of treating large numbers of the London County Council's school children, and we were able to place before our readers a representative body of medical opinion upon an admittedly difficult subject. At the same time we gave our own views on this important matter in a leading article,[2] whilst fully recognising the latitude of opinion which must necessarily prevail in a situation where the interests of the school children, the hospitals, the private medical practitioners of the Council's school area, and of the ratepayers are all concerned, and to som [illegible] tent are at cross purposes.

work was performed by, or on behalf of, medical men. Secondly, it was desirable that the committee should collect inform [illegible] practice of treating ailmer [illegible] pharmacists and by other [illegible] for these important duties.

Another interesting discussion was that opened by Mr. H. **WIPPELL GADD**, F.C.S., barrister-at-law, on Some Problems of the Poison Schedule.

Among the many interesting papers read we may refer to the following. Dr. W. **MARTIN** read a paper upon Some Experiences in the Testing of Drugs by Bio-chemical Methods, with Special Reference to Digitalis, Squill, and Strophanthus. Dr. Martin went minutely into a subject which was rather outside the pharmaceutical track and in conclusion referred to the idea, which seemed to be gaining ground, that some tests of a bio-chemical nature should be included in the Pharmacopœia. He understood that it would be a departure from the principles that had hitherto actuated the compilers of the British Pharmacopœia to include methods that could not be carried out by the pharmacist himself, and his own impression was that the time was not yet ripe for the introduction of tests of this kind, unless they were made permissive and not mandatory. If it were decided that the "frog test" was the most satisfactory method of estimating the therapeutic activity of certain drugs he thought it might be included, as the tests were of such a kind that they could be carried out quite well and with perfect propriety by men who were trained in the art of delicate manipulation and scientific observation.

The increase in the duty on alcohol probably suggested the subject of the paper read by Mr. W. B. **DOTT**, F.R.S.E., namely, "The Use of Alcohol in Pharmacy." Mr. Dott remarked that there had been manifest of late a distinct *tendency to reduce the proportion of spirituous preparations*. Comparing the 1885 with the 1898 Pharmacopœia he found the tinctures reduced from 72 to 65 and the liquid extracts increased from 12 to 17. The question arose: Could the proportion of alcohol used in pharmaceutical preparations be s[illegible] the medicinal value c[illegible] ould, and mentioned [illegible] with lower strength alcohol than that required by the Pharmacopœia The strength of alcohol used in making many extracts could also be reduced without disadvantage. He also discussed the value of glycerine and acetic acid as solvents.

The results of the analysis of a number of samples of "malt extract with cod-liver oil" were given by Mr. E. F. **HARRISON**, B.Sc., F.I.C. 19 samples were examined and the percentage of oil was found to vary from 1·5 to 30·5; the diastatic value of the extract varied from 7 to 776, [illegible] act from 53·6 to [illegible] reed that the very [illegible] things which was [illegible] ew of the public. [illegible] number of samples of "commercial emulsions" drawn from many sources. Some were dispensed at various pharmacies in London and the country, while others were purchased at random, but the majority of the samples were obtained direct from wholesale houses The emulsions varied roughly from 25 per cent. to 50 per cent. and were generally as described on the label; the manufacturers of those containing the lower amounts deemed any information unnecessary. He considered that in a complex mixture like an emulsion 10 per cent on the result would not be too liberal an allowance in judging accuracy.

Probably *no ointment introduced into the more recent* of the British Pharmacopœias has given so much trouble and dissatisfaction as the paraffin ointment at present official. Mr. J. H. **FRANKLIN** had conducted a number of experiments with a view to discover an ointment base to replace it and embodied the results in his paper on "Unguentum Paraffini." He suggested the following alternative formulæ:—

A.

White petroleum jelly	85 parts.
Pure bleached cerasin	15 "

B.

White petroleum jelly	82 parts.
Paraffin wax m p. 130° F.	8 "
Pure bleached cerasin	10 "

"B" is the whiter basis, but "A" is rather smoother.

Mr. C. **SYMES**, Ph.D., suggested an improvement on the pharmacopœial method for the manufacture of "fluid extract of cascara sagrada." The point of exhaustion of the bark is usually determined by the absence of bitterness in the percolate, but in working a small batch of 28 pounds of bark a short time ago it occurred to Dr. Symes that when bitterness of the percolate had ceased the addition of ammonia to a further portion of the menstruum might be the means of obtaining a further yield of extract possessing medicinal value. He found that the apparently exhausted bark did yield a percolate possessing distinct aperient properties when treated with diluted ammonia, and he described in detail the process employed.

Mr. W. A. H. **NAYLOR**, F.I.C., and Mr. E. J. **CHAPPEL** gave details of a process for the "estimation of extractive and glycerine in spirituous galenicals." The process depended on the removal of the glycerine and determination of the extractive by weighing the residue.—Mr. G. **PINCHBECK**, F.C.S., contributed a note on the "Separation of Strychnine from Brucine." The experiments described demonstrate that the United States Pharmacopœia assay process, modified in a manner proposed by the author, was capable of giving accurate results under conditions which were not onerous to the worker.—Mr. J. G. **REMINGTON** and Mr. H. **LANCASTER** communicated a paper on the "Comparative Examination of the Halogen Absorption of Oils by the Methods of Hubl, Wijs, Hanus, and McIlhenoy"; and Mr. D. **LLOYD HOWARD** and Mr. J. B. P. **HARRISON** described a method for the "Determination of Antimony in its Sulphide Preparations."

THE
TWELFTH INTERNATIONAL CONGRESS ON ALCOHOLISM.

(*Continued from p 251.*)

ON Thursday, July 22nd, the Congress met in the *Kensington Town-hall*, when Sir **THOMAS P. WHITTAKER**, M.P., read a paper on the Economic Effects of the Production and Consumption of Alcohol. The production of any article which gave employment to a large number of people, he said, was not necessarily a proof that such production was wise or valuable. If money was not spent in the production of liquor it would be available for other things which would give at least as much employment as the liquor trade now gave. The total expenditure on alcohol in this country was £165,000,000, and the value of that expenditure must be gauged from the point of view of the consumer. The real tests of the wisdom and value of this expenditure were two and were exemplified in these questions: (1) were these liquors beneficial? (2) could the consumer afford the expenditure? He went on to contrast the health and work of the teetotaler with that of the non-abstainer and, founding his arguments principally on insurance statistics, drew the conclusion that the abstainer did better work and was more healthy. Drink, he said, was the dominant factor in crime, pauperism, and disease.

Herr **KARL KOGLER** (Vienna), in a paper on Alcoholism and Industrial Assurance against Disaster and Invalidity, maintained that alcohol leads to degeneration of the race and consequently to an increase of risks in every class of workman's insurance.

In the evening, by the invitation of the Hon. and Very Rev. J. W. Leigh, Dean of Hereford, a garden party was held at the Grosvenor River Club, Henley-on-Thames.

On Friday, July 23rd, the Congress again met in the Kensington Town-hall, when Alderman F. S. **SPENCE** read a paper on "No License" Legislation, and Herr **VILTOR** read a paper on International Concert in Protecting Native Races from Alcoholism. After some discussion on these papers it was decided to send the following telegram to Mr. Chamberlain:—

[illegible]

The afternoon session was held at the Imperial Institute, when Professor LARS O. JENSEN (Bergen) dealt with the subject of Systems for the Control or Management for the Liquor Traffic. This paper had special reference to the Norwegian system of intrusting the sale of liquor to *samlags* or companies, and in the course of his remarks he said that the greatest decrease of drunkenness in Norway had taken place before the introduction of *samlags*, but, on the other hand, the *samlag* system prevented in a large measure the worst forms of drunkenness.

The Scientific Section met in the evening at the Imperial Institute, Dr. T. S. CLOUSTON (Edinburgh) dealing with the subject of the Resistive Power of the Brain against Alcohol, and Dr. F. W. MOTT (London) with the Effects of Alcohol upon the Nervous System.

The work of the Congress was concluded on Saturday, July 24th, with a final general meeting at the Imperial Institute. The papers read included Alcoholism and Crime, by Lieutenant-Colonel A. B. McHardy (Edinburgh); The Treatment of the Criminal Inebriate, by Professor G. Aschaffenburg (Cologne); and Legislation for the Inebriate, by Dr. R. W. Branthwaite (London).

Lieutenant-Colonel McHARDY brought forward statistics showing that in 1907 58,000 cases of simple drunkenness were reported to the police in Scotland, besides 32,000 cases of breach of the peace, for the most part brought about by excessive drinking. From the records of 153 cases ending in sentences for murder and culpable homicide it was shown that in 84 per cent. of these cases drink either generally or immediately was associated with the crimes.

Professor ASCHAFFENBURG maintained that legal penalties for the treatment of the criminal inebriate were usually insufficient. The drinker was suffering from a disease, and if he showed himself to be incurable he should be sentenced to perpetual custody in an asylum.

Dr. R. W. BRANTHWAITE spoke of the inelasticity of the law, but believed that there was reason to hope that the near future would show extensive changes in our system of dealing with the victims of drink.

It having been definitely decided that the next Congress should be held in 1911 at the Hague the proceedings were brought to a conclusion with the usual complimentary votes of thanks.

EPSOM COLLEGE.

FOUNDER'S DAY was commemorated at Epsom College on Saturday last, when, in spite of the frequent showers, there was a large attendance of relatives of the boys and of supporters of the College. There were also present several old Epsomians who were in the school during the head-mastership of the late Dr. Robinson Thornton, which lasted from the foundation of the College in 1855 to the year 1870, and Dr. Thornton's widow, daughter, and two sons. The proceedings began with a service in the chapel, at the close of which the Rev. Canon Curtis, an old boy, delivered a brief address and unveiled a window which has been erected in memory of Dr. Thornton by old Epsomians of his time and other friends of the College who appreciated his work at Epsom. The window, the cost of which was defrayed by subscriptions from old pupils, is placed on the south side of the chancel, and is designed to illustrate the events of Easter Day, that being the day on which the Archdeacon died. The three scenes are Christ's appearance to Mary Magdalene in the garden: "Touch Me not"; the Supper at Emmaus: "He was known to others in breaking of bread"; and Christ's appearance to St. Peter: "The Lord is risen indeed and hath appeared to Simon." The upper tier of lights contain single figures of Apostles and teachers suggesting different ideas of ministerial work: St. James, St. Peter, and St. Timothy, the proposal being to continue a series of figures in the other chancel windows. In the tracery lights are the arms of the University of Oxford and of St. John's College, Oxford, to which the late Archdeacon Thornton belonged. Mr. Percival Turner, with whom the scheme for the memorial window originated, has stated that his requests for subscriptions to the window fund, which were commenced shortly after Archdeacon Thornton's death at Easter, 1906, met with invariably prompt response.

The visitors afterwards assembled in the big schoolroom to hear the customary report by the Head-master, the Rev. T. N. H. Smith Pearse, on the work of the school for the year, and to witness the distribution of prizes by Sir Walter Foster. There were on the platform the Earl of Rosebery (President of the College), who personally presented his own prizes for modern history and English literature, Sir Henry Morris, Bart. (treasurer), Sir William S. Church, Bart. (chairman of the council); Sir Constantine Holman, the Rev. Canon Curtis, Dr. W. Collier, Dr. F. de Havilland Hall, Dr. F. Needham, the Rev. E. W. Northey, Mr. Clement L. Smiles, Mr. W. A. Propert, Dr. Guthrie Rankin, and Dr. F. Taylor.

In reviewing the work of the year the HEAD-MASTER drew attention to the fact that though the scientific successes of the College were well known, and special facilities existed for the preparation of students for the medical profession, it had always been his policy to broaden the education as much as possible, so that boys should enter various professions. He felt sure, therefore, that all present would be glad to hear that honours had been won by old Epsomians during the past year in the classical tripos, in the history tripos at Cambridge, and in the school of theology at Oxford. He referred to two special distinctions obtained by old Epsomians—namely, the baronetcy conferred upon Sir Henry Morris, late President of the Royal College of Surgeons of England, and the appointment of the Rev. R. H. Whitcombe as Bishop of Colchester. He said that, according to some newspapers, public schools nowadays must be judged by the size of their rifle corps, and Epsom College could stand being judged by this standard, since 133 boys, being 80 per cent of those eligible to join, were members. He deprecated the teaching of the elements of science to very young boys at the expense of such necessary subjects as Latin, English, and French. As evidence of what a school can do in science if boys are properly prepared in other subjects, he pointed out that during the past eight years no fewer than 46 Epsom boys have passed the preliminary scientific examination for the degree of M.B., B.S. of the University of London, and 33 have passed a part, only 16 candidates having failed.

After the distribution of the prizes Sir WALTER FOSTER delivered an address to the boys. He first congratulated Sir Henry Morris upon his baronetcy which had been well won by hard work. He then expressed his pleasure at coming to Epsom College, because he knew John Propert, its founder. As long as the medical profession flourished the name of Propert would be honoured, and Epsom College would have its share in the making of great Englishmen. He was struck by the beauty of the surroundings of the College and the opportunity that was given for healthy and invigorating games, while judging from the appliances for teaching and the character of the staff the College also gave the boys the opportunity of acquiring a healthy mind. Every head-master he had known always held before his pupils some ideal. When he was a boy the great ideal held out before him was duty. The lives of Nelson and Wellington had a wonderful influence in fixing the guiding principle of life, and no better teaching could be given to young people than that of devotion to duty. But duty done well required something more than mere mechanical adherence to rule. It should be done with foresight and knowledge, and the President of Epsom College, when he preached the doctrine of efficiency, extended and developed the old doctrine of duty. It was not given to everyone to be efficient, but it was given to them all to make the effort. Everyone should start with the idea that one of their principles of life must be the performance of duty, and should feel that in the performance of duty well and wisely done they contributed in the most effective way to the good of their country. In conclusion, he expressed his pleasure at finding that science took a leading part in the curriculum, and said that he was also delighted to know that the Head-master considered classical teaching to be the best way of building up vigorous mental power. In that College, therefore, the older learning would not be neglected, while the younger learning was welcomed and extended. Epsom College was helping to do a great work, and would, as it deserved, take a high place among the public schools of England.

At the conclusion of the address Sir HENRY MORRIS proposed a cordial vote of thanks to Sir Walter Foster for his kindness in visiting the College to address the boys. This was carried by acclamation, and Sir WALTER FOSTER briefly responded.

Amongst the honours gained direct from the school since last Founder's Day are an open science scholarship at Christ Church, Oxford, an open classical exhibition at Keble College, Oxford, and a pass into Woolwich (forty-second place). 19 boys have passed the matriculation examination of the University of London, and 19 have passed in the first class of the art examination held by the Society of Art Masters.

After leaving the schoolroom the visitors inspected the various new buildings, including the "Markham Skerritt" laboratories, erected through the kindness of the late Mrs. Markham Skerritt, which cost over £5000; the new lavatory block and the carpenter's workshop, all of which have been completed; also the new music block and gymnasium which are in process of erection.

METROPOLITAN HOSPITAL SUNDAY FUND.

AT a meeting of the Council of the Fund held at the Mansion House on July 28th it was announced that £67,212 were available for distribution. We hope to publish a list of awards in an early issue of THE LANCET.

The following are among the amounts which have been received at the Mansion House since our last issue:—

	£	s.	d.
[illegible]	439	0	0
[illegible] Vicarage-gate, [illegible]	315	0	0
[illegible]	261	0	0

ASYLUM REPORTS.

Monmouthshire Asylum, Abergavenny.—The total number of patients under treatment during the year ending March 31st was 1123 and the average number resident was 932. There were 98 patients discharged and of these 63 were recovered, the recovery rate for the year being 32·4 per cent. This rate is 6·4 per cent. lower than that obtained in 1907, and 4·4 per cent. lower than the average obtained in this asylum. The deaths during the year numbered 88 and the death-rate calculated on the average number resident was 9·4 per cent. At this asylum there is a great disproportion between the numbers of male and female patients. There are now 134 more male patients than female patients, and the male admissions during the year were nearly double the female admissions. This appears in part to be due to the increased industrial development in the mineral portion of the county. The statistical tables are presented in the new form and have entailed a large additional amount of labour, which it is hoped will enhance their value.

Leicester Asylum, West Humberstone.—The total number under treatment in this asylum for the year ending March 31st was 962, the average number resident being 732. The admissions during the year were 177. In the discharges, of which there were 254, the percentage of recoveries on the admissions was 48·2. The rate of mortality upon the average number resident was 7·1. At this asylum there were 142 epileptic patients under treatment and 11,554 fits were recorded.

County and City of Worcester Asylum, Powick.—The total number under treatment at this asylum for 1908 was 1107, the average number resident being 979. Discharges amounted to 84 patients, and of these 50 were discharged recovered. This gives the high percentage of 71·4 of recoveries, but this is explained by the small number of the admissions on which the percentage was calculated. The deaths numbered 69, being at the rate of 7·04 on the average number resident.

Down District Asylum, Downpatrick.—The total number of cases under treatment at this asylum for the year ending March 31st was 868, the daily average number resident being 739. The admissions numbered 143 and the discharges showed a recovery-rate of 49 per cent. The deaths numbered 40, giving a percentage of 6·8 on the daily average number resident. For the first year in the knowledge of Mr. M. J. Nolan, resident medical superintendent, there has been no case of dysentery, which in former years was a scourge in this asylum. It is hoped that in consequence of the various hygienic measures adopted by the committee the disease will not again assert itself. The report is illustrated with views of the exceedingly pleasant looking accommodation provided for the patients.

Lebanon Hospital for the Insane, Asfuriyeh, near Beyrout, Syria.—The report of this hospital was presented at the annual summer meeting for 1909. The work of the hospital represents the only attempt that has been made in Syria to provide for the mentally affected. The native methods of treatment of the insane appear to be both inadequate and cruel, and there can be no doubt that the work done at the hospital is worthy of all commendation. In the year reported on 122 patients were admitted to the hospital, making a total of 197 patients treated during the year. The discharges numbered 115 and of these 26 were recovered and 26 improved. To account for the large number of discharges it appears that the relations of patients insist on their removal long before they are really well. Those who would wish to learn more of the work of this medical mission can obtain copies of the report from the Secretary, at 35, Queen Victoria-street, London, E.C.

MEDICINE AND THE LAW.

The Liability of Hospitals to their Patients.

THE Court of Appeal recently delivered judgment upon a question of law of considerable importance to hospitals. In the action out of which the appeal arose the plaintiff, Mr. W. H. Hillyer, a medical man, sued the Corporation of the City of London, in their capacity of governors of St. Bartholomew's Hospital, for damages for injuries alleged to have been received by him through the negligence of themselves or their servants. He had been operated upon in the hospital and it was for injuries alleged by him to have been caused to him by the negligence of those concerned in the operation that he sought to recover damages. The decision of the court was delivered by Lord Justice Farwell, who, with regard to the main point of whether the surgeons, anæsthetists, and nurses present at and taking part in an operation are "servants" of the governors of a hospital, pointed out that the surgeons and anæsthetists are not under the direction of the governors or bound to obey their orders, and therefore cannot be regarded as being their servants for whose acts they would be liable. The governors were only subject to the obligation to use care and skill in selecting proper persons as members of the hospital staff. With regard to nurses, although primarily the servants of the governors, they took their orders from and were under the control of the surgeons during an operation, and thus in respect of duties so performed ceased to be the servants of the governors. His lordship, with regard to the case before the court, said that the appellant had not proved negligence on the part of those engaged in the operation, and that in order to obtain damages he had to prove such negligence on the part of persons for whom the respondents were answerable. At the trial[1] Mr. Justice Grantham had withdrawn the case from the jury on the ground that if there was negligence the defendants were not liable and that there was no evidence of negligence. The judgment delivered was concurred in by the Master of the Rolls and Lord Justice Kennedy and the appeal was dismissed.

Prosecutions for the Sale of Indecent Publications.

Two recent prosecutions resulting in the conviction of the offenders show that the question of the publication of demoralising and indecent jests, pictures, and advertisements is not being allowed to be forgotten, although the Government has not yet found time to legislate upon the lines suggested by the Joint Select Committee which reported in the summer of 1908. In both instances a periodical called *Photo Fun* was concerned, and in the first a defendant named Hemyng, described as its "responsible editor," was fined 40*s.* with 3 guineas costs. It will be remembered that the need of new provisions simplifying the procedure in these cases was dwelt upon by legal witnesses before the Select Committee. In this instance the editor was prosecuted not as such but for sending through the post a packet containing the matter complained of, a copy of his paper which, presumably, the police had ordered from him. We have before us a copy of *Photo Fun*, and its contents may fairly be said to justify the proceedings taken, although we do not know that our copy is of the incriminated issue. Its pictures and printed matter come within the definition suggested by a witness before the Joint Select Committee, as "directly suggesting immorality or promiscuous sexual intercourse, offensive to modesty or delicacy, lewd, unchaste or dissolute." Its advertisements are almost entirely of an objectionable character, the goods offered including preventives of conception, quack medicines and "remedies" for "ladies," for "weak men," and for those suffering from venereal disease, together with books or photographs either indecent or so described as to suggest that they are such. The second prosecution referred to was directed against a man named Burns, a newsagent in High Holborn, and was at the instance of the National Vigilance Association. The original search warrant was issued in connexion with a publication entitled *Photo Bits*, but copies of others, including *Photo Fun*, *Life*, and various French periodicals, were also laid before the court, and the possibility of proceedings against persons more directly responsible for their production than the newsagent was mentioned. On the summons issued the defendant was fined £10, with £3 3*s.* costs, and if this serves as a warning to others carrying on the same kind of business it should have a useful effect. None should have any sympathy with a corrupting and demoralising trade dangerous to the moral and physical health of the public. The report of the Joint Select Committee referred to, which was commented on in a leading article in THE LANCET[2] at the time of its issue, recommended that wider power to deal summarily with the publication of indecent matter should be given to magistrates, and that the determination of what is objectionable and indecent should be left to their discretion without any definition that would limit their powers to dealing only with what is grossly obscene. It also recommended that the advertisement and sale of drugs or articles which might reasonably be considered as designed for promoting miscarriage or for procuring abortion should be made illegal, and that it should be made illegal to advertise drugs or articles designed for the prevention of conception.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Liverpool.—The fact that the population of Liverpool, the second largest city in the kingdom, is only a little over 750,000 brings home to us the relative smallness of our own population as compared with the United States of America, where there are several cities reaching or nearly approximating a population of 1,000,000. But perhaps the time is [illegible] e of the large cities, such as Glasgow, [illegible], and Birmingham, will endeavour once again to extend their areas and thus bring about, by what may be termed compulsory artificial means, what they are by only a very long process able to accomplish by natural increase. Probably all the four cities mentioned could easily, if they could obtain power to extend, bring their populations up to 1,000,000, and thus for the moment exceed the population of Glasgow. The birth-rate of Liverpool for 1908 was 31·7 per 1000, the rates ranging from 18·2 to 39 2 per 1000 in the different districts Although the Liverpool birth-rate is, like that of the country as a whole, steadily decreasing, it is only exceeded by three of the towns having a population of over 100,000. The general death-rate of the city for 1908 was 18·2 per 1000, and it is of interest in relation to the general social circumstances of Liverpool to notice that the percentage of deaths which occur in public institutions is materially greater than in other towns, the proportion being for 1904–08 32·6 in Liverpool, as against 24·8 in Manchester, 28·4 in Birmingham, and 15·8 in Leeds. Dr. E. W. Hope points out that a high percentage of total deaths in institutions generally implies poverty and want, but that there is another explanation, and that is the popularity of the institutions. This is quite true, and it is not inconceivable that the condition of public institutions might be made so attractive that half the population or even more might elect to die within their walls. In 1884 the death-rate of Liverpool was over 26 per 1000, whereas now it is well under 19 per 1000. The infant mortality rate in 1908 was 140 per 1000 births, and in connexion therewith Dr. Hope very truly observes that "it must never be forgotten that, as regards feeding and care, whatever the municipality is able to do in regard to the preservation of infant life is insignificant when compared with what it is in the power of the mother to do If the mother will suckle the infant its risks are slight. If she will not do so the corporation proves but a poor foster-mother owing to the absolute impossibility of fulfilling the duties which only the mother herself can discharge" In several of Dr. Hope's reports emphasis has been laid upon the importance of the personal factor of the mother in the prevention of excessive infantile mortality; and in the report before us reference is made to the fact that, in 874 families concerning which inquiries were made by virtue of the death of an infant in such family, it was found that in these families there had been born 3801 infants, of whom, practically all in infancy, no less than 1895 had perished—an infantile mortality rate of 498 per 1000 births. Dr. Hope also refers to the influence which is exerted upon infantile mortality by the rapidity with which children follow one another, and where the next arrival may divert detailed attention from its predecessor almost before the first is weaned; and in connexion with this question of very high birth-rates reference is made to the returns of certain corporation dwellings built to accommodate persons displaced by the destruction of the slum areas in which they lived. The birth-rate in these dwellings, which are situated in an area where the birth-rate is 40 per 1000, was no less than 55 per 1000 during the last two years. There were 21 cases and 10 deaths from typhus fever in 1908, figures which rather suggest that some of the cases went undetected. Since the year 1902 there has been, as in many other large towns, a marked decline in the death-rate from enteric fever, and the same observation holds good with reference to the death-rate from pulmonary tuberculosis, as to which subject Dr. Hope makes some very statesmanlike comments. Referring to phthisis mortality in the corporation dwellings, he remarks that notwithstanding the history of the occupiers the mortality during 1907–08 was only 1·35 per 1000, a rate certainly lower than that of the city as a whole and very considerably below that of the districts in which the dwellings are situated. Holding the view that this low phthisis death-rate is the result of the good sanitary conditions provided by the corporation Dr. Hope adds: "No practical sanitarian would suggest that if instead of spending the money in demolishing the slums, purchasing the sites, and erecting the dwellings it had been spent in providing sanatoriums and in removing and maintaining the diseased people therein that the results would have been at all comparable either in benefit to the city or to the inmates of the dwellings themselves," and when we turn to the maps and illustrations of the corporation dwellings contained in the Liverpool report we cannot but express our agreement in the views set forth by the medical officer of health. The work of medical inspection of school children has now been established upon a satisfactory basis in Liverpool. It was at first proposed to establish a separate medical department to act under the Director of Education, but it was eventually determined that the medical officer of health should supervise the work.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8056 births and 3335 deaths were registered during the week ending July 24th The annual rate of mortality in these towns, which had declined in the six preceding weeks from 12·6 to 11·5 per 1000, further declined to the exceptionally low rate of 10·6 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these towns averaged only 11·3 per 1000, and in London during the same period it did not exceed 10·9. The lowest recorded annual death-rates last week in the 76 towns were 3·6 in Willesden, 4·4 in Smethwick, 4·8 in York, and 4 9 in Hornsey; the rates in the other towns ranged upwards, however, to 15·6 in Great Yarmouth, 16·3 in West Bromwich, 16 4 in Swansea, and 16·6 in Newport (Mon) In London the recorded death-rate last week did not exceed 10·0 per 1000, and was considerably lower than in any previous week of this year. The 3335 deaths from all causes in the 76 towns last week showed a further decrease of 302 from the declining numbers in recent weeks, and included 311 which were referred to the principal epidemic diseases, against 341 and 324 in the two preceding weeks; of these 311 deaths, 95 resulted from measles, 88 from diarrhœa, 51 from whooping-cough, 34 from diphtheria, 32 from scarlet fever, and 11 from "fever" (principally enteric), but not one from small-pox. The 311 deaths from these epidemic diseases last week were equal to an annual rate of 1·0 per 1000, corresponding with the rate in the previous week. No death from any of these epidemic diseases was registered last week in Bradford, Willesden, Brighton, Wallasey, Northampton, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·7 in West Bromwich, 3·8 in Bootle, 4·2 in Walsall, and 6·7 in Newport (Mon.). The 95 fatal cases of measles in the 76 towns showed a further considerable decline from the numbers returned in recent weeks; the highest annual death-rates from this disease last week were 2·3 in Bootle, 2·5 in Wolverhampton, 2·6 in Walsall, and 6·0 in Newport (Mon.). The deaths attributed to diarrhœa, which had steadily increased from 58 to 67 in the four preceding weeks, further rose to 88 last week, but were considerably below the average for the season. The 51 fatal cases of whooping-cough showed a further decline from the numbers in recent weeks, but caused annual rates equal to 1·1 in Walthamstow and in St. Helens, and to 1·3 in Southampton and in South Shields. The 34 deaths from diphtheria were within one of the numbers in the previous week, and included three in Manchester and Salford, and two both in Rochdale and in Newcastle-on-Tyne. Of the 32 fatal cases of scarlet fever ten occurred in London and its suburban districts, four in Liverpool, and three in Manchester and Salford. The deaths referred to "fever," which had been nine and 22 in the two preceding weeks, declined again last week to 11. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had steadily increased in the seven preceding weeks from 2228 to 2737, fell to 2731 on Saturday last; 367 new cases of this disease were admitted to these hospitals during last week, against 371 and 415 in the two preceding weeks. The registered deaths in London last week referred to pneumonia and other diseases of the respiratory organs, which had been 154 and 108 in the two previous weeks, rose again last week to 132, and exceeded by nine the corrected average number in the corresponding week of the five years 1904-08. The five deaths directly referred last week to i [illegible] previous week [illegible] of the deaths [illegible] certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during last week were again duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, Leicester, Salford, and in 54 smaller towns; the 22 uncertified causes of death last week in the 76 towns included five in Liverpool, three in London, and two each in Birmingham, Bootle, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 903 births and 448 deaths were registered during the week ending July 24th. The annual rate of mortality in these towns, which had been equal to 13·3, 12·9, and 12·5 per 1000 in the three preceding weeks, was again 12·5 in the week under notice. During the first three weeks of the current quarter the death-rate in these Scotch towns averaged 12·6 per 1000; in the 76 large English towns the mean death-rate during the same period did not exceed 11·3. The death-rates last week in these Scotch towns ranged from 7·9 in Leith and 11·2 in Edinburgh and in Aberdeen, to 17·6 in Paisley and 19·8 in Perth. The 448 deaths in the eight towns last week corresponded precisely with the number returned in the previous week, and included 45 which were referred to the principal epidemic diseases, against 36 and 40 in the two preceding weeks. These 45 deaths were equal to an annual rate of 1·3 per 1000, against 1·0 and 1·1 in the two preceding weeks; the rate last week from the same epidemic diseases in the 76 large English towns did not exceed 1·0 per 1000. Of the 45 deaths last week from these epidemic diseases in the Scotch towns, 14 resulted from measles, 14 from diarrhœa, seven from whooping-cough, four from diphtheria, three from "fever," and three from scarlet fever, but not one from small-pox. The 14 fatal cases of measles showed a marked increase upon the numbers in recent weeks, and included six in Paisley and five in Edinburgh. The deaths attributed to diarrhœa, which had been 12 and 11 in the two preceding weeks, increased to 14 last week; eight were returned in Glasgow, three in Dundee, and two in Edinburgh. The seven fatal cases of whooping-cough showed a considerable decline from the numbers in recent weeks; three occurred in Glasgow and two in Edinburgh. The four deaths from diphtheria were fewer by two than those in the previous week, and two of the three fatal cases of scarlet fever occurred in Glasgow. The three deaths referred to "fever" included a fatal case of typhus in Glasgow and one of cerebro-spinal meningitis in Edinburgh. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 71, 61, and 56 in the three preceding weeks, further declined to 49 in the week under notice, and were one below the number in the corresponding week of last year. The deaths in the eight towns last week included 17 which were referred to different forms of violence, of which nine occurred in Glasgow, four in Dundee, and two in Edinburgh. The causes of 26, or 5·8 per cent., of the deaths in the eight towns last week were uncertified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 15·6 and 16·9 per 1000 in the two preceding weeks, declined to 14·4 in the week ending July 24th. During the first three weeks of the current quarter the death-rate in the city averaged 15·6 per 1000, whereas the mean rate during the same period did not exceed 10·9 in London and 12·6 in Edinburgh. The 110 deaths of Dublin residents from all causes last week showed a decline of 19 from the number returned in the previous week, and included nine which were referred to the principal epidemic diseases, against three and 11 in the two preceding weeks. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rate from the same epidemic diseases last week being equal to 0·8 in London and 1·0 in Edinburgh. Of the nine deaths from these epidemic diseases in Dublin last week, four resulted from diarrhœa, two from "fever," two from whooping-cough, and one from diphtheria, but not one from measles, scarlet fever, or small-pox. The four deaths attributed to diarrhœa were fewer by one than the number in the previous week. The 110 deaths at all ages [illegible] 24 of infants under one year of age and 24 of persons aged upwards of 60 years; the deaths of elderly persons showed a considerable decline from the numbers in recent weeks. Nine inquest cases and six deaths from violence were registered during the week; and 48, or 43·6 per cent., of the deaths occurred in public institutions. The causes of four, or 3·6 per cent., of the deaths in the city last week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all but three of the 926 deaths were duly certified, while in Edinburgh the proportion of uncertified causes of death was equal to 4·0 per cent.

THE SERVICES.

THE NEW DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE.

Surgeon-General William Launcelotte Gubbins, C.B., M.V.O., has been appointed Director-General in succession to Sir A. H. Keogh, K.C.B. Surgeon-General Gubbins entered the service in 1885 and reached the rank of Colonel in 1900. He was appointed Surgeon-General in 1903. He served in the Afghan war of 1878–80, and took part with the Bazar Valley expedition under Lieutenant-General Maude in medical charge of the 5th Fusiliers, and subsequently of the headquarters staff; in 1879–80 he served with the Khyber Line Force under Lieutenant-General Bright in medical charge of the headquarters staff; he was also divisional sanitary officer and secretary to the Principal Medical Officer, and was present with the expeditions against the Mohmunds and into the Hissarik Valley (medal). He served with the Egyptian (1882) and Burmese (1886) expeditions, and in the South African war in 1899–1901 as principal medical officer of the 6th Infantry Division. He was present at the relief of Kimberley, the actions at Paardeberg, Poplar Grove, Driefontein, and the occupation of Bloemfontein. He took part in the operations in Orange River Colony, and was subsequently principal medical officer of Pretoria and the northern line of communication (medal with five clasps).

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeons: G. Ley to the *Juno*, and D'A. Harvey to the *Highflier*, on recommissioning. Staff-Surgeons: A. C. Bean to the *President*, additional, as inspecting medical officer, auxiliary sick berth staff; C. H. Rock to the *President*, additional, to be lent to Yarmouth Hospital, temporary; N. H. Harris to the *Shannon*, P. T. Sutcliffe to the *Defiance*, and F. T. Lobb to the *Victory*, additional, for disposal; R. H. Mornement to the *Eclipse*; J. G. Watt to the *Hermione*, on recommissioning; J. E. H. Phillips to the *Roxburgh*, on recommissioning; and R. S. Bernard to the *Apollo*, on recommissioning. Surgeons: C. J. O'Connell to the *Roxburgh*, on recommissioning; G. T. Verry to the *Flora*, additional; and W. E. Ormsby to the *Halcyon*, additional, for the *Skipjack*.

ROYAL ARMY MEDICAL CORPS.

Captain H. D. Packer has taken over the duties of embarkation and disembarkation medical officer in Plymouth Garrison.

Major Charles W. Duggan retires on retired pay (dated July 28th, 1909).

The undermentioned Captains to be Majors (dated July 28th, 1909): Charles H. Hopkins, Arthur W. N. Bowen, William H. S. Nickerson, V.C., Hubert O. B. Browne-Mason, and Frederick S. Penny.

Lieutenant-Colonel G. E. Moffet, retired pay, has been granted leave of absence from August 2nd to 31st, with permission to travel in Germany.

Lieutenant-Colonel Sir Joseph Fayrer, medical officer of the Duke of York's School, has been selected for duty at Hong-Kong.

INDIAN MEDICAL SERVICE.

Captain H. C. Brown, I.M.S., Brigade Laboratory, Dera Ismail Khan, has been appointed a specialist in prevention of disease.

TERRITORIAL FORCE.

Royal Field Artillery.

3rd West Riding Brigade: Surgeon-Captain Percival Ellison Barber, from the 4th West Riding of Yorkshire, Royal Garrison Artillery (Volunteers), to be Surgeon-Captain, with precedence as in the Volunteer Force (dated April 1st, 1908).

Royal Army Medical Corps.

1st Highland Field Ambulance: John Douglas Fiddes to be Lieutenant (dated June 10th, 1909).

2nd North Midland Field Ambulance: Richard Milbourne West (late Captain, 5th Northern General Hospital, Royal Army Medical Corps) to be Lieutenant (dated June 9th, 1909).

1st Wessex Field Ambulance: Lieutenant Alexander W. F. Sayres to be Captain (dated June 13th, 1909).

5th Northern General Hospital: Captain Richard M. West resigns his commission (dated June 9th, 1909).

3rd Southern General Hospital: Officers whose services are available on mobilisation:—Arthur Latham Ormerod to be Captain (dated July 10th, 1909).

1st Welsh Field Ambulance: Lieutenant John F. Dwyer resigns his commission (dated June 17th, 1909).

Attached to Units other than Medical Units.—Captain Charles K. Bowes resigns his commission (dated June 15th, 1909).

For Attachment to Units other than Medical Units—Lionel Danyers Bailey to be Lieutenant (dated July 19th, 1909). The announcement of the transfer of Surgeon-Major Joseph Edward Bowser and of Surgeon-Lieutenant John Livingstone from the Westmorland and Cumberland Imperial Yeomanry is cancelled. Surgeon-Lieutenant-Colonel (Honorary Major in the Army) William John Naismith, D.S.O., from the Ayrshire (Earl of Carrick's Own) Imperial Yeomanry, to be Lieutenant-Colonel, with precedence as in the Imperial Yeomanry (dated April 1st, 1908). Lieutenant-Colonel (Honorary Major in the Army) William J. Naismith, D.S.O., is retired under the provisions of Paragraph 59, Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated April 28th, 1909). Henry Randall Wadd to be Lieutenant (dated June 7th, 1909). Lewis Beesly to be Lieutenant (dated June 17th, 1909). Thomas Henry La Nauze Hewitt to be Lieutenant (dated June 23rd, 1909). Thomas Francis Roche to be Lieutenant (dated June 23rd, 1909).

Officers Training Corps.

Oxford University Contingent, Medical Unit, Senior Division: Captain Walter T. Brooks to be Major (dated July 12th, 1909).

THE UNIVERSITY OF LONDON TRAINING CORPS.

The military education committee of the University of London Officers Training Corps has issued a handbook for the use of officers and cadets and others concerned. It contains the Regulations of the Senate of the University of London for the military education committee, the names of the committee, rules of admission, and lists of members of the different units. The syllabuses of the different examinations for certificates are also included in the pamphlet.

The statue of the late Sir James McGrigor, Bart., first Director-General of the Army Medical Department, has been removed from the Chelsea Hospital to the new Royal Army Medical College in Grosvenor-road.

Surgeon-General H. R. Whitehead, C.B., Principal Medical Officer, Southern Command, inspected the barracks and hospitals at Exeter on July 26th, Taunton on July 27th, and Trowbridge on July 28th.

Correspondence.

"Audi alteram partem."

THE ROUTINE USE, BY THE OPEN METHOD, OF A MIXTURE OF CHLOROFORM AND ETHER

To the Editor of THE LANCET.

SIR,—Dr. A. Goodman Levy's letter in your issue of July 17th constitutes a valuable addendum to our joint report on the above subject published by us in your columns of July 3rd, and answers certain of the criticisms advanced by your correspondents in your issue of July 10th. The work which

Dr. Levy has done is of great interest as bearing directly upon the method we have advocated. We find ourselves unable to agree with Dr. Donald J. Munro as to there being any disadvantages whatever *in practice*, dependent upon the fact that ether and chloroform have different rates of vaporisation, provided that the mixture we advocate be administered as we have described. Instead of meeting with irregular effects, as might theoretically be supposed, we have obtained regular and equable results. Dr. J. D. Mortimer criticises our use of the terms "open" and "semi-open." We think Dr. Levy's letter will justify the distinction we draw between these two expressions. We are interested to learn that Dr. Desborough Brodie has employed the method we advocate, and with equally good results. Dr. Alexander Brown asks whether it is our opinion that the administration of C.E. mixture by the open method should supersede its administration by means of an inhaler devised by one of us. The fact is that when that inhaler was introduced the possibility of obtaining adequate anæsthesia *in all subjects* by means of the C.E. mixture administered from a Skinner's mask was not fully appreciated, and the passage in the work referred to by Dr. Alexander Brown therefore needs slight modification. At the same time, the inhaler in question, by reason of its wide air-inlet, is greatly to be preferred in point of safety to others of the Rendle type. Now, however, that the practicability of obtaining adequate anæsthesia by a simple Skinner's frame of particular dimension and construction is established, there is not that necessity for a semi-open inhaler with wide air-inlet that previously existed. Finally, we come to Dr. G. A. H. Barton's remarks. After directing attention to all absence of novelty in our contribution—which, we are sure, he will see is our misfortune rather than our fault—he suggests one or two improvements in our method. These, however, appear to us to be rather on the side of complexity than on that of simplicity. We do not ourselves attach great importance to rapidity of induction, except in certain special types of subject, believing that the best kind of anæsthesia *during operation* is to be obtained by gradual rather than by rapid induction methods. At the same time, we tender him and all your other correspondents our best thanks for discussing a subject which we think is of importance to all who administer anæsthetics, and particularly to those practitioners to whom simplicity of procedure specially commends itself.—We are, Sir, yours faithfully,

FREDERIC HEWITT.
J. BLUMFELD.

NATIONAL UNION OF ASSISTANT PHARMACISTS.

To the Editor of THE LANCET.

SIR,—I am instructed to forward you a copy of the protest which has been sent to the Pharmaceutical Society on behalf of our union.—I am, Sir, yours faithfully,

S. CARLTON FARRER, M.P.S.,
Honorary General Secretary.

Birmingham, July 13th, 1909.

[COPY.]

To the Pharmaceutical Society, London.

[illegible] members of the National [illegible] ully considered the com- [illegible] othecaries asking *for* the [illegible] s' Certificate to the rank [illegible] ection in pharmacy most vitally affected by the proposition made therein, and as members of the Pharmaceutical Society and registered chemists and druggists, we hereby emphatically protest against their entrance on any such terms; and we respectfully urge upon you as our representatives to secure to us the utmost possible protection from such unfair competition.

[illegible] knowledge.

(2) The whole period of training need not exceed six months, as contrasted with the three years minimum required of candidates for the Minor qualification.

(3) No preliminary examination is demanded, thus reducing the educational standard below that which would be required for entrance to any profession.

(4) The skill and knowledge required for examination as published in [illegible] onal value of the [illegible] ing condition be

"That whilst the Pharmaceutical Society is willing to register candidates as pharmaceutical *chemists* or *chemists and druggists* who can show that they have passed an examination equivalent to the major and minor examinations respectively, conducted by any responsible examining body such as the 'Society of Apothecaries,' 'The Civil Se[illegible] Colonial body, they would call [illegible] Apothecaries to the fact that [illegible] 'evidence satisfactory to the [illegible] Society that they are persons [illegible] to be so registered,' and the [illegible] Assistants' Certificate for a peri[illegible] *not satisfy such requirements.*"

[illegible] vithout corresponding registration under the [illegible] t you will give that [illegible] our request demands [illegible] is to many assistant [illegible]

(Signed)

A CERTIFICATE OF THE CAUSE OF DEATH FOLLOWED BY AN INQUEST.

To the Editor of THE LANCET.

SIR,—The annotation in THE LANCET of July 24th, p. 243, under this heading raises the question as to whether the medical man in attendance during the last illness of a person has the power to decide whether he shall give a certificate of death or not. In that annotation you write: "The far more frequent cause of complaint against medical men arises out of the withholding of certificates which cannot conscientiously be granted, but which in the opinion of the coroner or the jury would save the necessity of an inquest." As a matter of fact, the medical man has no such discretionary power. It is obligatory upon him to certify the cause of death even if violent. Section 20 of the Births and Deaths Registration Act, 1874 (37 and 38 Vict., c. 88), is most explicit upon this point. By that section it is enacted:—

> In case of death of any person who has been attended during his [illegible]

It is a great pity that this fact is not fully appreciated and acted upon by medical men. The duty of the medical man would simply be that of signing a certificate in all cases of death, whether due to natural or violent causes. The unpleasant, responsible, and unremunerated work of deciding whether an appeal to the coroner is necessary would thus fall upon the registrar, where it is meant to fall by the Act. The medical man would then be saved those awkward situations you quote. I am, Sir, yours faithfully,

EDWIN J. TOYE.

July 26th, 1909.

RE-INFECTION IN SYPHILIS.

To the Editor of THE LANCET.

SIR,—If you will excuse this belated letter I should like to make a few comments on Mr. Hutchinson's interesting and instructive article in THE LANCET of May 29th on Auto-inoculation and Re-infection in Syphilis, which I have only just seen. In the first place, it is only fair to the memory of Ricord to mention that in later life he recanted some of his earlier statements—for instance, the non-contagiousness of secondary lesions. With regard to the question of re-infection, he made the following remarks in a letter to Mr. W. Acton (published in the *British Medical Journal*, 1872, Vol. II., p. 228): "Now that we have authentic examples of fresh contagions of indurated chancre, with consecutive evolution of the whole series of constitutional symptoms, this proves that patients have been cured, just as the possibility of contracting small-pox afresh or of vaccination again taking proves that the first variolous or vaccine influence has ceased." Mr. Hutchinson attributes the intermittent method of mercurial treatment to Ricord, but I think it was Fournier who introduced the "chronic intermittent treatment" of syphilis. Whether, as Mr. Hutchinson suggests, this method is less efficacious in curing syphilis than the continuous method, and consequently less likely to be followed by re-infection, is a moot point which would require much evidence to decide. With regard to infection of the subjects of inherited syphilis with the acquired disease, the late Professor Tamowsky published a number of cases of this kind which he called "binary syphilis," and considered that this combination has a more lethal effect on the offspring of such subjects than inherited syphilis by itself. As I pointed out in my book on "Syphilology and Venereal Disease," it may be possible for a patient who has had two attacks of syphilis to be suffering from the effects of both attacks at the same time, for parasyphilitic effects, such as tabes or general paralysis due to the first attack, may appear after the date of re-infection. It is true that Krafft-Ebing obtained negative results from the inoculation of general paralytics with syphilis, but I believe authentic cases of syphilitic chancres in the subjects of general paralysis have been recorded.—I am, Sir, yours faithfully,

C. F. MARSHALL.

St. John's Wood Park, N.W., July 25th, 1909.

MALTA FEVER ON THE RIVIERA.

To the Editor of THE LANCET.

SIR,—Referring to Dr. J. K. Fowler's letter in THE LANCET of July 24th (p. 254), I remember well a case of Malta fever I attended three and a half years ago at Cannes. I made careful inquiries at the time and I think that a similar sequence of events to that recorded was not very uncommon with regard to the Riviera generally about that time. The evidence is not in my own experience and I give the impression resulting from my inquiries for what it is worth. In my own case, which was also an undoubted one, I was quite unable to find the source of infection, though I tried carefully to do so.—I am, Sir, yours faithfully,

R. NEVILLE HART, M.D. Cantab.

Bournemouth, July 24th, 1909.

A VEGETABLE SOURCE OF IRON.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 17th there is an interesting annotation (p. 164) on a vegetable source of iron. The observations of two French workers are quoted as showing that the dried root of the dock, *Rumex obtusifolius*, contains 0·447 per cent. of iron in a combination analogous to the ferric derivatives of the nucleones. It is perhaps worth while observing that such a preparation of iron with nucleins as a base has recently been obtained which contains as much as 8·0 per cent. of iron. It is called *Fer Ascoli*, and I can speak with confidence as to its value in the treatment of anæmic girls.—I am, Sir, yours faithfully,

A. BUTLER HARRIS, M.A., M.B. Oxon.

Loughton, Essex, July 25th, 1909.

TROPICAL ADENITIS AND PLAGUE.

To the Editor of THE LANCET.

SIR,—In connexion with the annotation on Tropical Adenitis and Plague which appeared in THE LANCET of June 12th (p. 1701), I may say that, prior to our plague visitation, we had many cases of bubo which were certainly not plague buboes nor the usual ordinary bubo—simple or venereal. I mentioned this fact to Professor Simpson, and he told me that in Calcutta these premonitory buboes had also been noticed just before a plague outbreak.

I am, Sir yours faithfully,

A. MARIUS WILSON, M.D. Durh.

Cape Town, July 6th, 1909.

THE MEDICAL TREATMENT OF LONDON COUNTY COUNCIL SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—The attention of my committee has been drawn to the statement in the published report of the meeting of the Education Committee of the London County Council held on July 14th, referred to in THE LANCET of July 17th, that the "Paddington Green Children's Hospital will take 20 ophthalmic cases a week." I am requested to inform you that this statement is incorrect, and that no such offer has been made from this hospital.

I am, Sir, yours faithfully,

W. H. PEARCE, Secretary.

Paddington Green Children's Hospital, London, W., July 24th, 1909.

⁂ The authority for the statement was the preliminary report of the Education Committee of the London County Council.—ED. L.

THE TERRITORIAL MEDICAL SERVICE.

(FROM A SPECIAL CORRESPONDENT.)

I. ORGANISATION.—DUTIES IN CAMP.

THE following notes are intended as an "appreciation" of the medical organisation of the Territorial Army, in so far as routine duties and sanitation in camps of exercise are concerned, and the relationship of these to active service in the field. Questions connected with the removal of sick and wounded will not be included.

Organisation.

Each division of the Territorial Army is commanded by a General Officer (G.O.C.), and on his staff is appointed an Administrative Medical Officer (A.M.O.) with the rank of colonel, who is a Territorial medical officer. The G.O.C. is the responsible head of the entire division, and the A.M.O. is responsible to him for the efficiency of all the medical *personnel* and equipment in his division for war, as well as for the physical efficiency and health of the entire division. He is the recognised adviser to the G.O.C. on all questions connected with the health and sanitation of the division, and he is also commanding officer (O.C.) of all the Territorial R.A.M.C. in the division. To assist the A.M.O. two staff officers (medical) are allowed, one being a retired field officer of the R.A.M.C., and the other a specialist sanitary officer or medical officer of health from the Territorial Medical Force. A permanent office and clerical establishment are also allotted. Each unit (regiment, battery, &c.) in the division has a Territorial medical officer attached, who is responsible for the physical and medical efficiency of his unit and also for the sanitation of the area they occupy. The Senior Medical Officer of each brigade (S.M.O.) is responsible in the same way for the brigade as a whole. Orders connected with general medical questions and sanitation affecting the entire division are issued by the A.M.O. in the name of the G.O.C., while purely professional orders are issued in his own name. Likewise orders affecting brigades alone or units alone are issued in the name of their respective commanders by the S.M.O. or M.O. respectively, and purely professional orders in their own names. The A.M.O. of a division, S.M.O. of brigade, and M.O. of regiments make inspections of their respective charges, each having in view sanitation of area, physique of the men, their freedom from disease, ventilation, clothing, cleanliness, food, and purity of drinking water. The sick and wounded are treated in hospitals (field ambulances, general hospitals, &c.), and while in hospital the patients are under the command of the medical officer in charge. Each hospital is a unit in itself and bears the same relationship to the G.O.C. and brigade commander as any other unit under their charge. Three field ambulances are allotted to each division, one to each of its brigades; the mounted brigade field ambulance is a smaller unit. The remaining medical unit is the general hospital which trains with the division in peace but belongs to the corps troops in war.

The P.M.O. of an army corps, the A.M.O. of a division, the S.M.O. of a brigade, and the M.O. of a unit are the respective advisers of their commanders on all questions concerning the health and sanitation of their respective charges.

Duties in Camp.

One of the most important duties of Territorial medical officers will be the education of all officers and men of their units in the essentials of camp and personal sanitation. From the time they enter camp, the conditions of civilian life (which have aptly been compared by a distinguished army sanitarian to the turning of a tap for a pure water-supply and the pulling of the handle of a modern water-closet for disposal of excreta, with municipal plumbers at hand to remedy defects) are left behind, and new conditions prevail which, if not carefully attended to, will prove a source of danger, not only to the individual, but to the entire community under canvas. The two essential principles of camp sanitation either on manœuvres or on active service are, firstly, the immediate burial or destruction of all excreta and refuse, and, secondly, the strict preservation of all water-supplies from contamination. The *laissez faire* fashion in which some officers used to treat these subjects has been a matter of comment, as well as the general apathy which until recently prevailed in the rank and file in matters of sanitation, the principles of which still provide virgin soil for the Territorial medical officers to work on. The starting-point of all sanitary education in the regular army begins now in the officer at Sandhurst and in the recruit at the depôt, and each officer on promotion is now forced to pass an examination in elementary sanitation. The rank and file are very thoroughly instructed in all matters relating to elementary hygiene and sanitation, and all ranks of the Territorial Army must be the same. The routine sanitary measures laid down for the life of the Territorial in camps of exercise will be carried in their minds, to a greater or lesser degree, on service in the field, and finally back again into civilian life.

If a unit has a "chief" strict as to the details of sanitation, not only of his camp and its environment, but also of the personal hygiene of his men during training, we may rely on it that such a unit will be "fit" and in good serviceable condition when put to the test of war. If, on the other hand, you find his tents on manœuvres and their occupants neglected in these matters, such a condition of affairs will never tend to improve on service, but rather get worse, and this unit will invariably break down with enteric fever or other fell dirt disease. Until such time as Territorial regimental officers take these matters up (and they must take them up), their colleagues in medical and sanitary charge of every unit will have to share responsibility with company officers for the following duties:—

1. The physical, sanitary, and medical efficiency of their units.

2. The training of such units in the rudiments of elementary sanitation.

3. The training of, and supervision of, the "sanitary squad" in latrine making, camp conservancy, and especially the conservancy of water-supplies.

4. Strict supervision of cook-houses, cooking vessels, and cooks, the latter especially in camp, where their methods ought to be gone into most fully and studied. All men of a unit should get some sort of practice in field cooking, as on service individuals may have to cook for themselves.

5. The instruction of the "first aid" *personnel* of the unit.

Every unit should be medically inspected as often as feasible during training, the men being paraded and the medical officer walking round and carefully scrutinising each man. In some cases the men are paraded on the parade ground with jackets unbuttoned, with or without shirt open and chest exposed, or again, jackets may be off and shirt sleeves rolled up with arms and forearms bare, extended, and supinated and pronated alternately, as the inspecting officer walks down the ranks. Or, again, inspection may be made in mounted corps as they finish stables, or when not in camp in the drill hall. Wherever an inspection is made its thoroughness must be essential, and to ensure this, where climatic conditions, such as exposure to sun, rain, or wind, may prevent it, a drill hall, marquee, or sheltered shed may be suggested as the proper place, thus ensuring comfort to the men and a more efficient and thorough inspection to the [illegible] edical [illegible] ny, to [illegible] when going round he [illegible] missioned officer [illegible] this officer should [illegible] not available owing to more urgent work to attend to (which ought not to be always the case), he should send his understudy (assistant adjutant) and always one or two junior officers of the regiment for instruction in military hygiene.

It is necessary, if sanitary measures are to be efficiently adopted in the army, to obtain help from regimental officers, and, if medical officers are to get practical assistance, the regimental officers must see and be made to understand how sanitary measures are carried out, and be pointed out defects in all matters relating to camps, food, clothing, and everything pertaining to the hygiene of barracks and the health of the soldier. Young regimental officers in some cases my perhaps take an unfavourable view of such compulsory instruction at first, but if tact is used, and the medical officer shows quietly but firmly that it is in their own interests that they should come and pick up these facts, matters which they will be thoroughly examined in later on for promotion, and of which more can be taught in a five minutes' explanatory walk round than could be understood in weeks of reading, success is certain. The medical officer should not play the rôle of a schoolmaster; let him rather make the task interesting by asking a few questions as to the regulation amount of the various kinds of rations, scales of clothing, &c., and point out how meat is judged and the difference between old and young meat by the bones; or again, let him draw attention to defects in the physique of the soldier, such as hammer toe and varicose veins, explaining their cause and simple remedy; if this be done he will find, as the writer has found, that all officers will not look on such a "walk round" as a bore, but will turn up again and again, and begin to really take an interest in this branch of their profession.

Medical inspections of units are not made for fun by the particular medical officer making them, though some people seem to think he has nothing to do but "hunt bad smells" in or around barracks. Such visits are made in accordance with the special orders laid down in the King's Regulations, and should such inspections be omitted or fail in thoroughness, a medical officer could, if necessary, be severely punished in the same way as an officer commanding a regiment could also be punished if he neglected to carry out rules laid down for prevention of disease when they had been recommended to him. A medical officer inspecting tents or men is not a faddist; he is, or at any rate he should be, thoroughly earnest; he is the person responsible for the health of the troops, and he is the person who should lose his commission if the work is neglected, unless he delegates his responsibility by reporting the matter to "higher authority." As long as there is no such report, higher authority takes it for granted "all is well," and trusts the medical officer; if the latter abuse this trust by not reporting matters that are not remedied regimentally, he can be court-martialled.

Medical inspection of [illegible] peace time should be made [illegible] em of passing a complete unit [illegible] actory from a medical officer's point of view, and a nuisance to every one concerned regimentally. If on such occasions the men are numbered off it may often be found that a large proportion of the regimental strength are not accounted for on parade. The important point about the absentees is that we know full well that it is among them the very men we want most to see are to be found—the men who do not, for reasons best known to themselves, wish to see their medical officer. The best way out of this most apparent frustration of medical inspection is to do away with the supposed, and it is maintained impossible, inspection of a unit as a whole unit. Even if a unit were mustered at full strength on parade, the task of proper inspection would be too much for one medical officer, who has his other routine work to do as well in the same morning. Every unit is divisible: if artillery into sections, if infantry into companies, and if cavalry into squadrons. Let these sub-units parade, let one company of an infantry regiment parade alone at as full strength as possible one day; let another company parade the next, and so on, and let the inspection be thorough and searching. Have a roll with the names of the absentees on each parade prepared by the orderly-sergeant, and let him hand it to the medical officer inspecting, who should keep it for reference; and let the absentees come up for inspection on the next or following days to the same medical officer at some place appointed by him—for instance, the hospital—and let him examine and mark them off as examined on his roll. Thus a regiment or other unit can be given a clean and true "bill of health," say once a training.

The day and hour for medical inspection should be carefully selected to suit all parties concerned; the day chosen should not, if possible, interfere with any of the men's ordinary duties or recreations, and the hour fixed should not delay meals. The men should parade with their jackets off; shirts and vests should be open in the front and rolled back sufficiently wide to show as much of the chest as possible; and shirt sleeves should be rolled high up above the elbows. Shirt inspections are important, especially on manœuvres, where men should be advised to wear either flannel shirts or "greybacks," and discard linen and cotton ones or singlets, all of which are dangerous when wet or when worn abroad under khaki drill in the sun. The cleanliness of the shirt, and its wearer, can also be ascertained, as well as some idea of the upkeep and replenishment or otherwise of these articles, which, unfortunately, are not a Government issue as in the regular army. In a drill hall, men for inspection should have their boots and socks off, and their trousers rolled up above the knee so as to fully expose the calves of their legs. Boots and socks should be laid on the ground for further inspection, as to fit and repair, if necessary. Feet inspections are most essential and should be carried out as frequently as possible; their first benefit is cleanliness. If men expect feet inspections they will prepare for them beforehand. The many irregularities in feet, bunions, corns, and ingrowing toe-nails which lead to men breaking down on the march, can be looked for and pointed out to the company chiropodist for attention (chiropodists should be appointed as in the regular army); the inside of the ankles can be glanced at for itch, a most common place for it to originate in army life.

The men having paraded in the dress just described the medical officer should commence at the front rank man of the first file, and walk down the front line, the men at the same time extending their arms and pronating and supinating their forearms alternately as he passes, in order that he may see both aspects of the arm. Boils, blind or otherwise, are often found in the mounted troops and should not escape notice. A general glance at each man's hair, face, teeth, and chest, carried on to the forearms and feet, occupies but a few seconds. The chest should be scanned for tinea versicolor, a not uncommon skin complaint in the service, due to men wearing unwashed flannel next the skin; it is a harmless, though unsightly, disease and tends to spread rapidly. Having inspected the front rank and having perhaps noted irregularities such as want of cleanliness in regard to the teeth or other matters, the front rank should be directed to take one pace forward, and the medical officer should walk back again behind the front rank inspecting the backs of their legs for varicose veins and take a general glance at head and neck for boils, and also have a glance at their clothing as to its fit, and whether trousers are too tightly braced up, &c. The rear rank is inspected in like manner to the front rank, after which the men can be dismissed and their camp inspected.

Tents should have their flies (kanats) rolled up first thing in the morning and left open all day, weather permitting. Men should leave the door open at night, and the maximum number of men sleeping in a tent should not exceed 12. Before rain, trenches should be dug round tents and side drains should carry away surface water. In fine weather tents should be struck at least once every four days and pitched on a new area. If tent boards are used they should be removed at the same time and the ground swept and exposed to bright sunshine for purification. All bedding should be spread out in the sun and aired daily.

The tents should be frequently inspected and all matters appertaining to general cleanliness, ventilation, washing utensils, beds and bedding, and hair- and tooth-brushes looked into. A medical officer should know exactly the number or scale of articles of clothing and bedding allowed to each man and how often they should be renewed, changed, and washed, and he should ask questions of these matters of the young regimental officers who should accompany him on his rounds. If necessary, a closer medical inspection should be made to eliminate infectious and rupture cases amongst the men of a unit; such a proceeding must always be rigidly enforced prior to active service, as if these cases are not weeded out they will assuredly break down in a campaign and fill the hospitals.

On the relationship that should exist between a medical officer of a unit and the commanding officer of his unit, there is little to comment on. The medical officer is the staff officer in all matters appertaining to the health and sanitation of the unit; he should advise on all matters tending to the health efficiency of the troops under his immediate charge, and keep a special eye on any of the weaker recruits and satisfy himself that they are not being overworked with drill, gymnasium, &c., and also see that the men have proper recreation, outdoor and indoor; as such advantages keep the men from vice and liability to contract disease, especially venereal disease. When under canvas all officers commanding units should be immedially informed by their medical officers of the appearance of any particular infectious disease, more especially enteric fever, among any of the men of their units, or other person in the locality, in order that they may assist their medical officers in every possible way to stamp out the disease, and prevent its extension in their own and to other units of the army. This is essential, for if we are to fight successfully against enteric fever in the field it is of the greatest importance that practice should take place in time of peace, with the same means and on the same scale, if possible, as in war time; and also the more we see of enteric fever in peace time the greater will our experience be for epidemics in a campaign.

(To be continued.)

THE ORGANISATION OF THE MEDICAL PROFESSION IN GERMANY: THE STRUGGLE AT COLOGNE.

(FROM OUR SPECIAL COMMISSIONER.)

Cologne, July, 1909.

THE work of organising the medical profession in Germany for the defence of its economic interests has been taken in hand at a comparatively recent date, though there have been medical societies in existence for some 40 years. Further, these local societies were federated together under the title of the Deutscher Aerztevereinsbund. Nearly all the local societies of medical men are members of this amalgamation or bond and it holds an annual congress, Der Deutsche Aerztetag. Many local societies are not unlike the local medical societies that exist in various parts of England. They are highly respectable institutions where scientific papers are sometimes read and pleasant dinners organised, but which have never achieved anything whatsoever in regard to the great economic struggles of the day. Even when these local societies united one with the other and held annual congresses they did not do anything that was likely to produce a practical result. If there was a crying grievance this amalgamation might appeal to the authorities and perhaps even went so far as to draw up and present a petition. Beyond this, however, it did not venture. At last, some eight years ago, Dr. Hartmann of Leipsic took the initiative in organising a fighting union. He explained that protests, petitions, and complaints were of no use whatsoever unless there was a force behind them that could make itself unpleasantly felt if no attention was paid to the demands brought forward. For this purpose he enrolled members and they paid an annual subscription of £1. The society was named the Organisation des Verbandes der Aerzte Deutschlands, but is more familiarly and generally called the Leipziger Verband. Its object is to watch over the economic interests of the medical profession, and its success in quickly recruiting members is due to the undoubted fact that the economic condition of the profession is getting worse and worse every year. When the society had been in existence three years it was found that the subscriptions paid by the members did not supply a sufficiently large capital to enter upon any very great struggle, and it was determined to raise £25,000 in shares bearing 5 per cent. interest, or in donations. Many donations were made, varying in amount from 1*s.* to £50. But large sums were required, as medical men had to be helped who were suffering because they had *obeyed* the orders of their union, while it was also sometimes expedient to buy off those competing against the organised members of the profession.

The Leipziger Verband, however, is not merely organised for the purpose of strikes. It has a central bureau or exchange, which acts as an agency to secure employment for medical practitioners. While it seeks to prevent medical practitioners accepting employment under contract and on conditions opposed to the principles of the medical profession, it, on the other hand, endeavours to find employment that is in accordance with the rules and under conditions considered legitimate. Further, the Verband comes to the rescue of the widows and children of its members. Though only eight years old, this society has now carried everything before it. Finally, and quite recently, the Deutscher Aerztevereinsbund has joined the Verband, so that the joint membership now amounts to about 23,000 medical men. There are in the German Empire something like 30,000 qualified medical men, but as this includes military surgeons, professors at universities, and others who are not in practice, there are probably not more than from 2000 to 3000 active practitioners who are not in the union. Nor is the organisation limited to qualified practitioners; it has permeated the ranks of the medical students. Thus time is taken by the forelock, and the student taught what his duties will be when he has passed his examinations. This is a most practical and useful precaution, for it is the young, inexperienced, newly qualified practitioners who often accept the offers made without realising the evil consequences that will result to themselves and to their profession. There are not only the offers made for contract work in respect to the working classes, but in various towns middle-class and well-to-do sections of the community have endeavoured to constitute themselves into friendly societies and contract for medical attendance. Thus the scope for private practice would be still further restricted. As it is, one-third of the population of Germany is removed by law from private practice as they come under the scheme for compulsory insurance. This applies to those whose incomes do not exceed £100 per annum. But if the people who have larger incomes are going to organise schemes of voluntary insurance little or nothing will remain. Therefore, all the members of the Verband are pledged not to treat with or accept employment in the service of any such mutual insurance association or middle-class friendly society.
